1

Δομές Ευρετηρίου: Διάρθρωση Διάλεξης

- Εισαγωγή - κίνητρο
- Ανεστραμμένα Αρχεία (Inverted files)
- Δένδρα Καταλήξεων (Suffix trees)
- Αρχεία Υπογραφών (Signature files)
- Σειριακή Αναζήτηση σε Κείμενο (Sequential Text Searching)
- Απάντηση Επερωτήσεων “Ταιριάσματος Προτύπου” (Answering Pattern-Matching Queries)

## Signature files (αρχεία υπογραφών)

### Αρχεία Υπογραφών (Signature Files)

Κύρια σημεία:

- Δομή ευρετηρίου που βασίζεται στο **hashing**
- Μικρή χωρική επιβάρυνση (**10%-20%** του μεγέθους των κειμένων)
- Αναζήτηση = σειριακή αναζήτηση στο αρχείο υπογραφών
- Κατάλληλη για όχι πολύ μεγάλα κείμενα

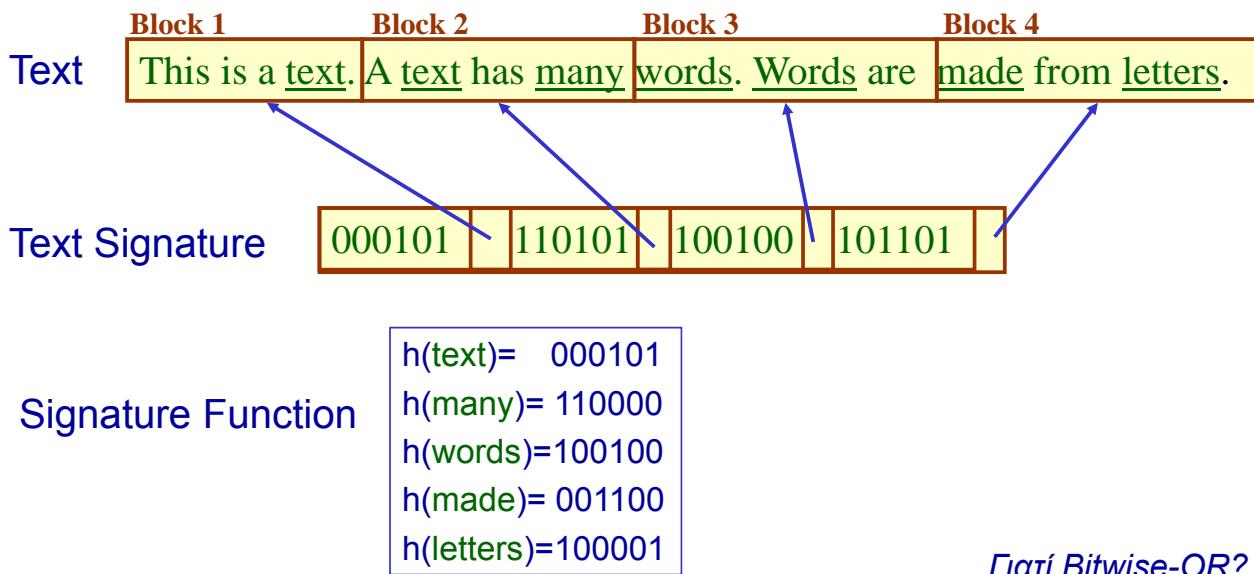

Συγκεκριμένα

- Χρήση **hash function** που αντιστοιχεί λέξεις κειμένου σε bit masks των  $B$  bits
- **Διαμέριση** του κειμένου σε blocks των  $b$  λέξεων το καθένα
- Bit mask of a block = **Bitwise OR** of the bits masks of all words in the block
- Bit masks are then concatenated

## Αρχεία Υπογραφών: Παράδειγμα

**b=3** ( 3 words per block) **B=6** (bit masks of 6 bits)

## Αρχεία Υπογραφών: Αναζήτηση

Έστω ότι αναζητούμε μια λέξη  $w$ :

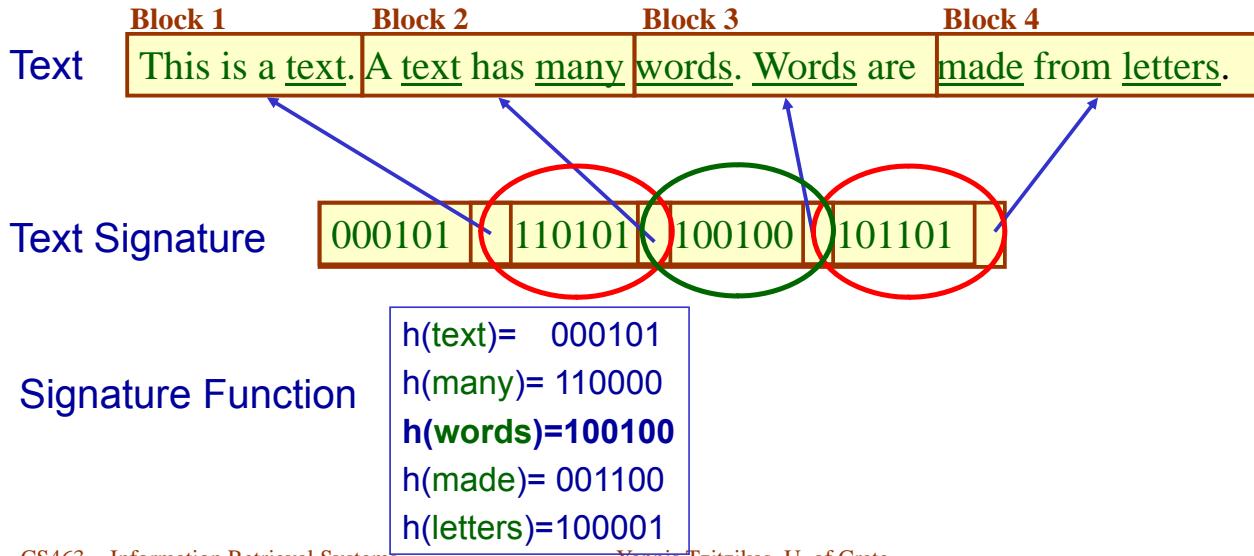

- 1/  $W := h(w)$  (we hash the word to a bit mask  $W$ )
- 2/ Compare  $W$  with all bit masks  $B_i$  of all text blocks  
If  $(W \& B_i = W)$ , the text block  $i$  is **candidate** (may contain the word  $w$ )
- 3/ For all candidate text blocks, perform an online traversal to **verify** that the word  $w$  is actually there

## False drops (false hits)

- False drop: All bits of the  $W$  are set in  $B_i$  but the word  $w$  is not there

$w=«\text{words}»$ ,  $h(«\text{words}»)=100100$

## Διαμόρφωση (Configuration) υπογραφών

- Σχεδιαστικοί στόχοι:
  - Μείωσε την πιθανότητα εμφάνισης **false drops**
  - Κράτησε το μέγεθος του αρχείου υπογραφών **μικρό**
    - δεν έχουμε κανένα false drop αν  $b=1$  και  $B=\log_2(V)$
- Παράμετροι:
  - $B$  (το μέγεθος των bit mask)
  - $L$  ( $L < B$ ) το πλήθος των bit που είναι 1 (σε κάθε  $h(w)$ )
- The (space)-(false drop probability) tradeoff:
  - 10% space overhead => 2% false drop probability
  - 20% space overhead => 0.046% false drop probability

## Αρχεία Υπογραφών: Άλλες Παρατηρήσεις

- **Μέγεθος αρχείου υπογραφών:**
  - bit masks of each block plus one pointer for each block
    - (pointing to the corresponding position at the original text)
- **Συντήρηση αρχείου υπογραφών:**
  - Η προσθήκη/διαγραφή αρχείων αντιμετωπίζεται εύκολα
    - προσθέτονται/διαγράφονται τα αντίστοιχα bit masks

## Signature files: Phrase and Proximity Queries

- **Good for phrase searches and reasonable proximity queries**
  - this is because **all the words** must be present in a block in order for that block to hold the phrase or the proximity query. Hence the **OR** of all the query masks is searched
- **Remark:**
  - no other patterns (e.g. range queries) can be searched in this scheme

## Phrase/Proximity Queries and Block Boundaries

q=<information retrieval>

Text blocks

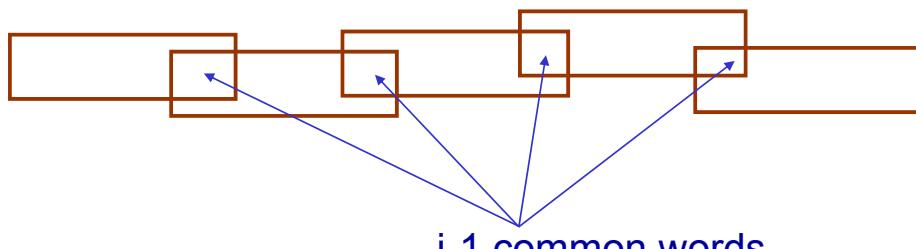

(πρόβλημα! Μπορούμε όμως να το λύσουμε με επικαλυπτόμενα blocks)

Overlapping blocks

For j-proximity queries

CS463 - Information Retrieval Systems

## Δομές Ευρετηρίου: Διάρθρωση Διάλεξης

- Εισαγωγή - κίνητρο
- Inverted files (ανεστραμμένα αρχεία)
- Suffix trees (δένδρα καταλήξεων)
- Signature files (αρχεία υπογραφών)
- **Sequential Text Searching**
- Answering Pattern-Matching Queries

## Σειριακή Αναζήτηση Κειμένου: Το πρόβλημα

find the first occurrence (or all occurrences)  
of a string (or pattern)  $p$  (of length  $m$ ) in a string  $s$  (of length  $n$ )

Commonly,  $n$  is much larger than  $m$ .

Χρήσεις:

- Για εύρεση των εγγράφων που περιέχουν μια λέξη (αν δεν έχουμε ευρετήριο).
- Στην περίπτωση που έχουμε ανεστραμμένο ευρετήριο με block addressing.
- Στην περίπτωση που έχουμε αρχείο υπογραφών για να βεβαιωθούμε ότι ένα match δεν είναι false drop.

## Sequential Text Searching Algorithms

- Brute-Force Algorithm
- Knuth-Morris-Pratt
- Boyer-Moore family

## Brute-Force Algorithm

*Brute-Force (BF), or sequential text searching:*

- Try all possible positions in the text. For each position verify whether the pattern matches at that position.
- Since there are  $O(n)$  text positions and each one is examined at  $O(m)$  worst-case cost, the worst-case of brute-force searching is  **$O(nm)$** .

## Brute-Force Algorithm

```
Naive-String-Matcher(S,P)
n := length(S)
m := length(P)
for i = 0 to n-m do
    if P[1..m] = S[i+1 .. i+m] then
        return "Pattern occurs at position i"
    fi
od
```

The naive string matcher needs worst case running time  $O((n-m+1) m)$

For  $n = 2m$  this is  $O(n^2)$

Its average case is  $O(n)$  (since on random text a mismatch is found after  $O(1)$  comparisons on average)

The naive string matcher is not optimal, since string matching can be done in time  $O(m + n)$

## Knuth-Morris-Pratt & Boyer-Moore

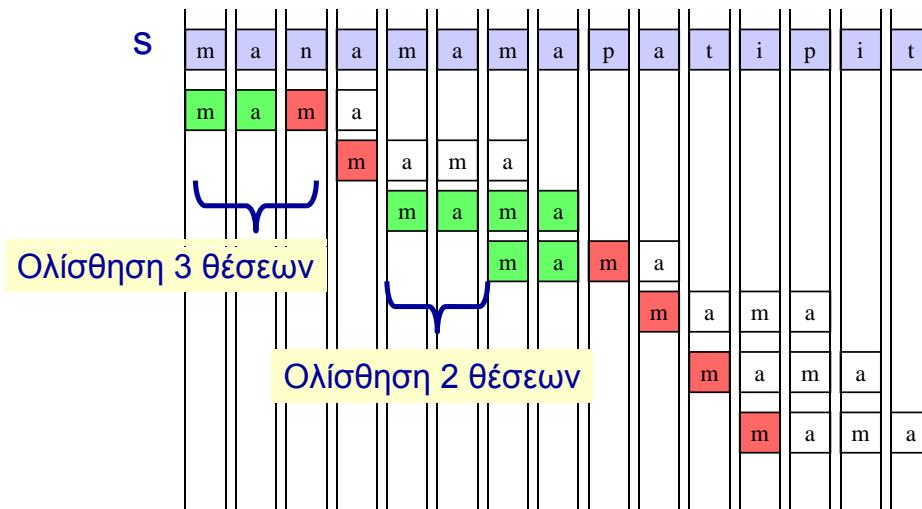

## Knuth-Morris-Pratt & Boyer-Moore

- Πιο γρήγοροι αλγόριθμοι που βασίζονται σε **μετακινούμενο (ολισθαίνον) παράθυρο**
- Γενική ιδέα:
  - They employ a **window** of length  $m$  which is slid over the text.
  - It is *checked* whether the text in the window is equal to the pattern (if it is, the window position is reported as a match).
  - Then, the window is shifted forward.
- Οι αλγόριθμοι διαφέρουν στον τρόπο με τον οποίο ελέγχουν και ολισθαίνουν (μετακινούν) το παράθυρο.

## Ολίσθηση Παραθύρου: Η γενική ιδέα

$p = "mama"$

- It does not try all window positions as BF does. Instead, it reuses information from previous checks.

## Knuth-Morris-Pratt (KMP) [1970]

- The pattern  $p$  is preprocessed to build a table called  $next$ .
- The  $next$  table at position  $j$  says which is the longest proper prefix of  $p[1..j-1]$  which is also a suffix and the characters following prefix and suffix are different.
- Hence  $j-next[j]-1$  window positions can be safely skipped if the characters up to  $j-1$  matched and the  $j$ -th did not.

## KMP: the next table

$\text{next}[j]$  = longest proper prefix of  $p[1..j-1]$  which is also a suffix and the characters following prefix and suffix are different

|                  |   |   |   |   |   |   |   |   |   |    |    |
|------------------|---|---|---|---|---|---|---|---|---|----|----|
| j                | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 |
| $p[j]$           | a | b | r | a | c | a | d | a | b | r  | a  |
| $\text{next}[j]$ | 0 | 0 | 0 | 0 | 1 | 0 | 1 | 0 | 0 | 0  | 4  |

## KMP: the next table

$\text{next}[j]$  = longest proper prefix of  $p[1..j-1]$  which is also a suffix and the characters following prefix and suffix are different

|                  |   |   |   |   |   |   |   |   |   |    |    |
|------------------|---|---|---|---|---|---|---|---|---|----|----|
| j                | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 |
| $p[j]$           | a | b | r | a | c | a | d | a | b | r  | a  |
| $\text{next}[j]$ | 0 | 0 | 0 | 0 | 1 | 0 | 1 | 0 | 0 | 0  | 4  |

## KMP: the next table

$next[j]$  = longest proper prefix of  $p[1..j-1]$  which is also a suffix and the characters following prefix and suffix are different

| j         | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 |
|-----------|---|---|---|---|---|---|---|---|---|----|----|
| $p[j]$    | a | b | r | a | c | a | d | a | b | r  | a  |

| $p[j]$           | a | b | r | a | c | a | d | a | b | r  | a  |
| $\text{next}[j]$ | 0 | 0 | 0 | 0 | 1 | 0 | 1 | 0 | 0 | 0  | 4  |

## KMP: the next table

$\text{next}[j]$  = longest proper prefix of  $p[1..j-1]$  which is also a suffix and the characters following prefix and suffix are different

| j                | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 |
|------------------|---|---|---|---|---|---|---|---|---|----|----|
| $p[j]$           | a | b | r | a | c | a | d | a | b | r  | a  |
| $\text{next}[j]$ | 0 | 0 | 0 | 0 | 1 | 0 | 1 | 0 | 0 | 0  | 4  |

## KMP: the next table

$\text{next}[j]$  = longest proper prefix of  $p[1..j-1]$  which is also a suffix and the characters following prefix and suffix are different

| j                | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 |
|------------------|---|---|---|---|---|---|---|---|---|----|----|
| $p[j]$           | a | b | r | a | c | a | d | a | b | r  | a  |
| $\text{next}[j]$ | 0 | 0 | 0 | 0 | 1 | 0 | 1 | 0 | 0 | 0  | 4  |

## KMP: the next table

$\text{next}[j]$  = longest proper prefix of  $p[1..j-1]$  which is also a suffix and the characters following prefix and suffix are different

| j                | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 |
|------------------|---|---|---|---|---|---|---|---|---|----|----|
| $p[j]$           | a | b | r | a | c | a | d | a | b | r  | a  |
| $\text{next}[j]$ | 0 | 0 | 0 | 0 | 1 | 0 | 1 | 0 | 0 | 0  | 4  |

## KMP: the next table

$next[j]$  = longest proper prefix of  $p[1..j-1]$  which is also a suffix and the characters following prefix and suffix are different

| j         | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 |
|-----------|---|---|---|---|---|---|---|---|---|----|----|
| $p[j]$    | a | b | r | a | c | a | d | a | b | r  | a  |
| $next[j]$ | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 1 | 0 | 0  | 4  |

## KMP: the next table

$next[j]$  = longest proper prefix of  $p[1..j-1]$  which is also a suffix and the characters following prefix and suffix are different

| j         | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 |
|-----------|---|---|---|---|---|---|---|---|---|----|----|
| $p[j]$    | a | b | r | a | c | a | d | a | b | r  | a  |
| $next[j]$ | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 1 | 0 | 0  | 0  |

## KMP: the next table

$\text{next}[j]$  = longest proper prefix of  $p[1..j-1]$  which is also a suffix and the characters following prefix and suffix are different

| j                | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 |
|------------------|---|---|---|---|---|---|---|---|---|----|----|
| $p[j]$           | a | b | r | a | c | a | d | a | b | r  | a  |
| $\text{next}[j]$ | 0 | 0 | 0 | 0 | 1 | 0 | 1 | 0 | 0 | 0  | 4  |

## KMP: the next table

$\text{next}[j]$  = longest proper prefix of  $p[1..j-1]$  which is also a suffix and the characters following prefix and suffix are different

| j                | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 |
|------------------|---|---|---|---|---|---|---|---|---|----|----|
| $p[j]$           | a | b | r | a | c | a | d | a | b | r  | a  |
| $\text{next}[j]$ | 0 | 0 | 0 | 0 | 1 | 0 | 1 | 0 | 0 | 0  | 4  |

## Exploiting the next table

$\text{next}[j]$  = longest proper prefix of  $p[1..j-1]$  which is also a suffix and the characters following prefix and suffix are different

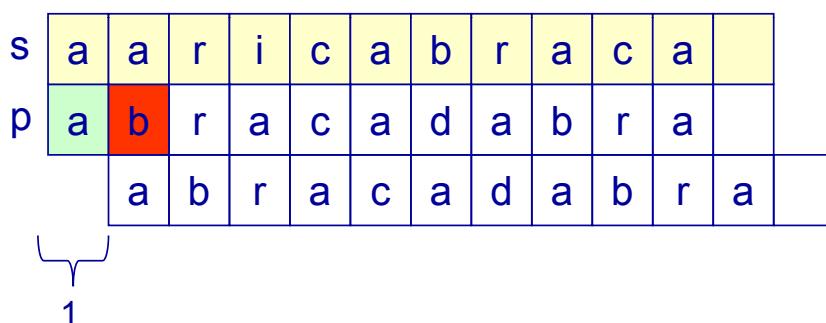

| j                    | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 |
|----------------------|---|---|---|---|---|---|---|---|---|----|----|
| $p[j]$               | a | b | r | a | c | a | d | a | b | r  | a  |
| $\text{next}[j]$     | 0 | 0 | 0 | 0 | 1 | 0 | 1 | 0 | 0 | 0  | 4  |
| $j-\text{next}[j]-1$ | 0 | 1 | 2 | 3 | 3 | 5 | 5 | 7 | 8 | 9  | 10 |

- $j-\text{next}[j]-1$  window positions can be safely skipped if the characters up to  $j-1$  matched and the  $j$ -th did not.

## Example: match until 2nd char

| j                    | 1 | 2        | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 |
|----------------------|---|----------|---|---|---|---|---|---|---|----|----|
| $p[j]$               | a | b        | r | a | c | a | d | a | b | r  | a  |
| $\text{next}[j]$     | 0 | 0        | 0 | 0 | 1 | 0 | 1 | 0 | 0 | 0  | 4  |
| $j-\text{next}[j]-1$ | 0 | <u>1</u> | 2 | 3 | 3 | 5 | 5 | 7 | 8 | 9  | 10 |

## Example: match until 3rd char

|             |   |   |          |   |   |   |   |   |   |    |    |   |
|-------------|---|---|----------|---|---|---|---|---|---|----|----|---|
| j           | 1 | 2 | 3        | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 |   |
| p[j]        | a | b | r        | a | c | a | d | a | b | r  | a  |   |
| next[j]     | 0 | 0 | 0        | 0 | 1 | 0 | 1 | 0 | 0 | 0  | 4  |   |
| j-next[j]-1 | 0 | 1 | <u>2</u> | 3 | 3 | 5 | 5 | 7 | 8 | 9  | 10 | 7 |

|   |   |   |   |   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|---|---|---|---|
| s | a | b | a   | i | c | a | b | r | a | c | a |
| p | a | b | <span style="background-color: red;">r</span> | a | c | a | d | a | b | r | a |
|   | a | b | r   | a | c | a | d | a | b | r | a |

2

## Example: match until 7th char

|             |   |   |   |   |   |   |          |   |   |    |    |   |
|-------------|---|---|---|---|---|---|----------|---|---|----|----|---|
| j           | 1 | 2 | 3 | 4 | 5 | 6 | 7        | 8 | 9 | 10 | 11 |   |
| p[j]        | a | b | r | a | c | a | b        | r | a |    |    |   |
| next[j]     | 0 | 0 | 0 | 0 | 1 | 0 | 1        | 0 | 0 | 0  | 4  |   |
| j-next[j]-1 | 0 | 1 | 2 | 3 | 3 | 5 | <u>5</u> | 7 | 8 | 9  | 10 | 7 |

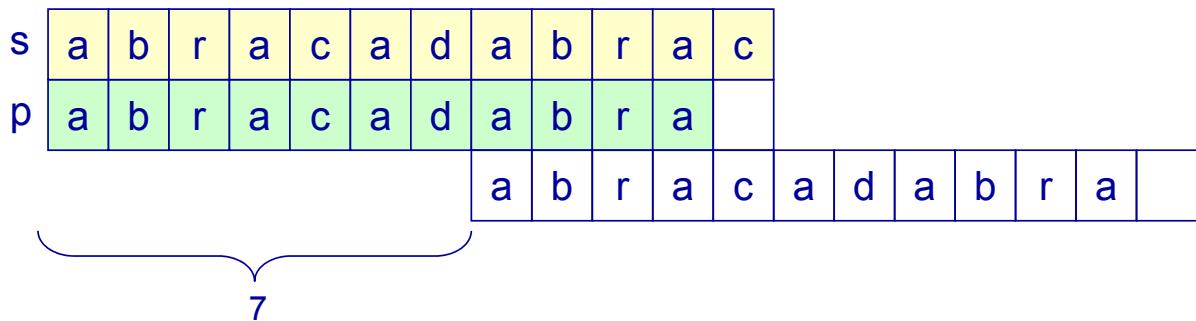

|   |   |   |   |   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|---|---|---|---|
| s | a | b | r   | a | c | a   | b | r | a | c | a |
| p | a | b | <span style="background-color: red;">r</span> | a | c | <span style="background-color: red;">d</span> | a | b | r | a |   |
|   | a | b | r   | a | c | a   | d | a | b | r | a |

5

## Example: pattern matched

| j           | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 |
|-------------|---|---|---|---|---|---|---|---|---|----|----|
| p[j]        | a | b | r | a | c | a | d | a | b | r  | a  |
| next[j]     | 0 | 0 | 0 | 0 | 1 | 0 | 1 | 0 | 0 | 0  | 4  |
| j-next[j]-1 | 0 | 1 | 2 | 3 | 3 | 5 | 5 | 7 | 8 | 9  | 10 |

## KMP: Complexity

- Since at each text comparison the window or the text pointer advance by at least one position, the algorithm performs at most  $2n$  comparisons (for the case where  $m=n$ ), and at least  $n$ .
- The overall complexity is  $O(m+n)$ 
  - The worst case is exactly  $n+m$  for finding the 1<sup>st</sup> occurrence
- Remarks:
  - We shouldn't however forget the cost for building the  $\text{next}$  table.
  - On average is it not much faster than BF

## Finite-Automaton-Matcher

## Finite-Automaton-Matcher

- For every pattern of length  $m$  there exists an automaton with  $m+1$  states that solves the pattern matching problem.
- *KMP is actually a Finite-Automaton-Matcher*

# Finite Automata (επανάληψη)

A deterministic finite automaton  $M$  is a 5-tuple  $(Q, q_0, A, \Sigma, \delta)$ , where

- $Q$  is a finite set of **states**
- $q_0 \in Q$  is the **start state**
- $A \subseteq Q$  is a distinguished set of **accepting states**
- $\Sigma$ , is a finite **input alphabet**,
- $\delta: Q \times \Sigma \rightarrow Q$  is called the **transition function** of  $M$

Let  $\varphi : \Sigma^* \rightarrow Q$  be the final-state function defined as:

For the empty string  $\varepsilon$  we have:  $\varphi(\varepsilon) := q_0$

For all  $a \in \Sigma$ ,  $w \in \Sigma^*$  define  $\varphi(wa) := \delta(\varphi(w), a)$

$M$  accepts  $w$  if and only if:  $\varphi(w) \in A$

## Example (I)

**Q** is a finite set of states

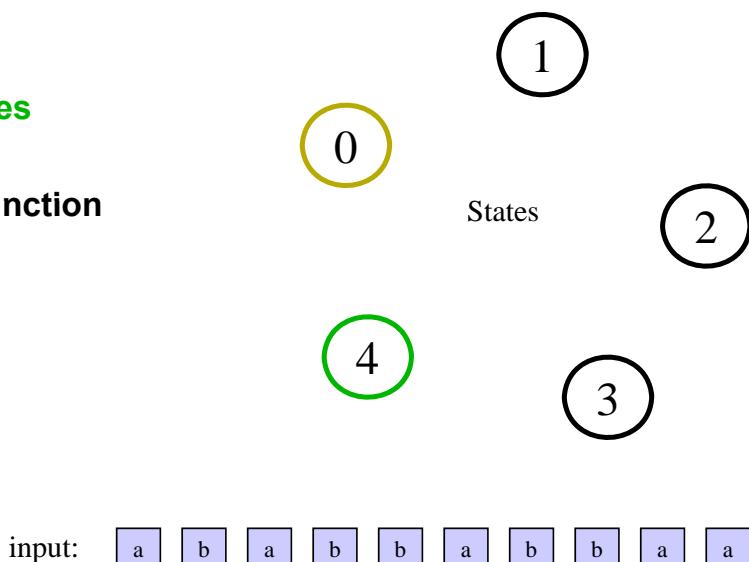

**$q_0 \in Q$**  is the start state

**$A$**  is a set of accepting states

**$\Sigma$** : input alphabet

**$\delta: Q \times \Sigma \rightarrow Q$** : transition function

$p=«abba»$

## Example (II)

**Q** is a finite set of states

$q_0 \in Q$  is the start state

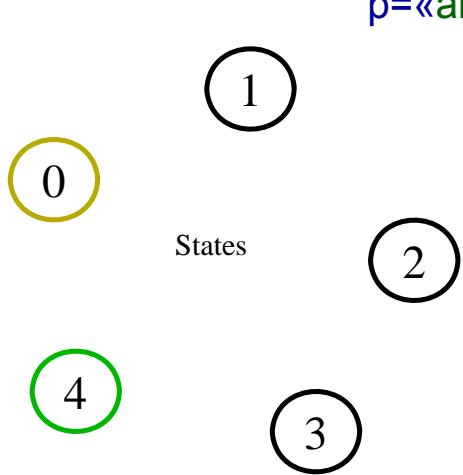

**Q** is a set of accepting states

$\Sigma$ : input alphabet

$\delta: Q \times \Sigma \rightarrow Q$ : transition function

| input | a | b |
|-------|---|---|
| state | 0 | 1 |
| 1     | 1 | 2 |
| 2     | 1 | 3 |
| 3     | 4 | 0 |
| 4     | 1 | 2 |

CS463 - Information Retrieval Systems

$p=«abba»$

States

43

Yannis Tzitzikas, U. of Crete

## Example (III)

**Q** is a finite set of states

$q_0 \in Q$  is the start state

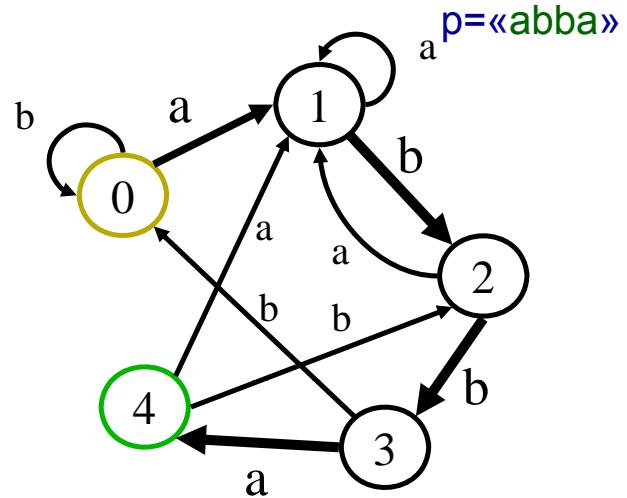

**Q** is a set of accepting states

$\Sigma$ : input alphabet

$\delta: Q \times \Sigma \rightarrow Q$ : transition function

| input | a | b |
|-------|---|---|
| state | 0 | 1 |
| 1     | 1 | 2 |
| 2     | 1 | 3 |
| 3     | 4 | 0 |
| 4     | 1 | 2 |

CS463 - Information Retrieval Systems

$p=«abba»$

Yannis Tzitzikas, U. of Crete

44

## Example (IV)

**Q** is a finite set of states

$q_0 \in Q$  is the start state

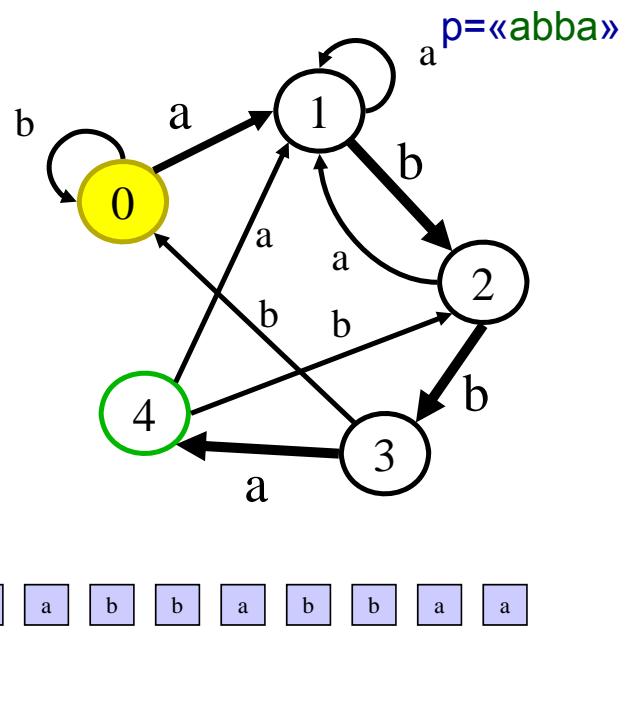

**Q** is a set of accepting states

$\Sigma$ : input alphabet

$\delta: Q \times \Sigma \rightarrow Q$ : transition function

| input \ state | a | b |
|---------------|---|---|
| state 0       | 1 | 0 |
| 1             | 1 | 2 |
| 2             | 1 | 3 |
| 3             | 4 | 0 |
| 4             | 1 | 2 |

CS463 - Information Retrieval Systems

Yannis Tzitzikas, U. of Crete

45

## Example (V)

**Q** is a finite set of states

$q_0 \in Q$  is the start state

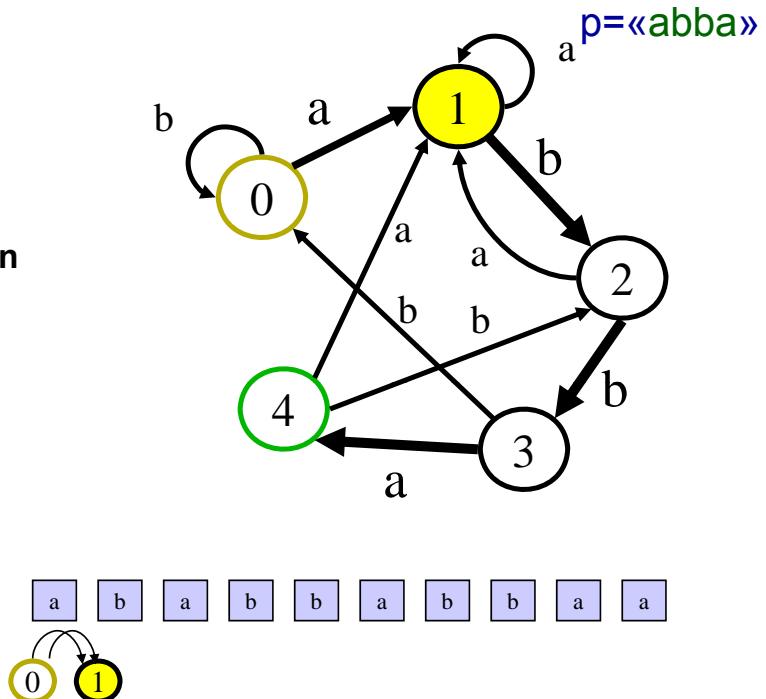

**Q** is a set of accepting states

$\Sigma$ : input alphabet

$\delta: Q \times \Sigma \rightarrow Q$ : transition function

| input \ state | a | b |
|---------------|---|---|
| state 0       | 1 | 0 |
| 1             | 1 | 2 |
| 2             | 1 | 3 |
| 3             | 4 | 0 |
| 4             | 1 | 2 |

CS463 - Information Retrieval Systems

Yannis Tzitzikas, U. of Crete

46

## Example (VI)

**Q** is a finite set of states

$q_0 \in Q$  is the start state

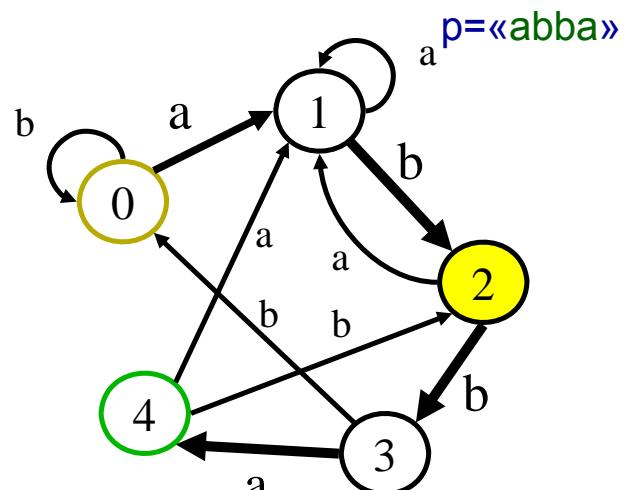

**Q** is a set of accepting states

$\Sigma$ : input alphabet

$\delta: Q \times \Sigma \rightarrow Q$ : transition function

| input | a | b |
|-------|---|---|
| state | 0 | 1 |
| 0     | 1 | 0 |
| 1     | 1 | 2 |
| 2     | 1 | 3 |
| 3     | 4 | 0 |
| 4     | 1 | 2 |

CS463 - Information Retrieval Systems

Yannis Tzitzikas, U. of Crete

47

## Example (VII)

**Q** is a finite set of states

$q_0 \in Q$  is the start state

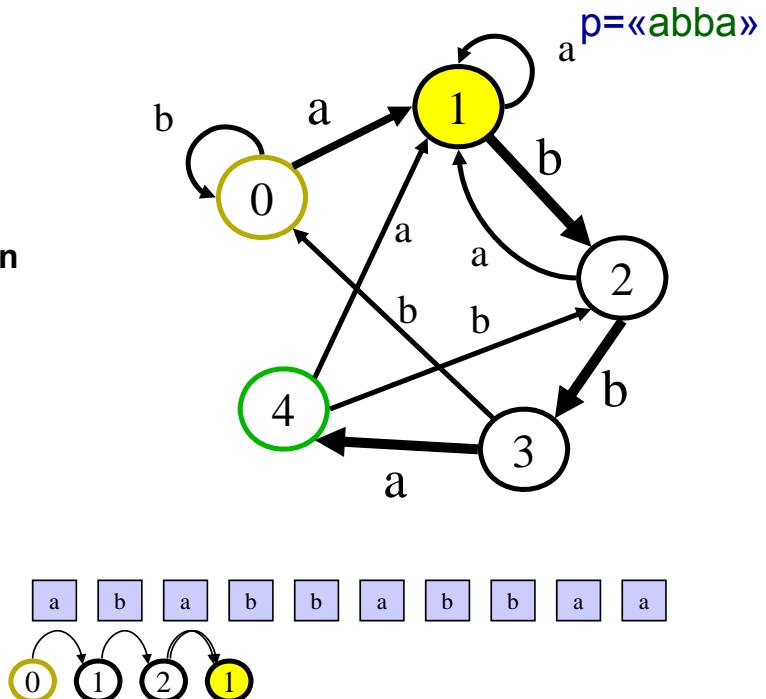

**Q** is a set of accepting states

$\Sigma$ : input alphabet

$\delta: Q \times \Sigma \rightarrow Q$ : transition function

| input | a | b |
|-------|---|---|
| state | 0 | 1 |

## Example (VIII)

**Q** is a finite set of states

$q_0 \in Q$  is the start state

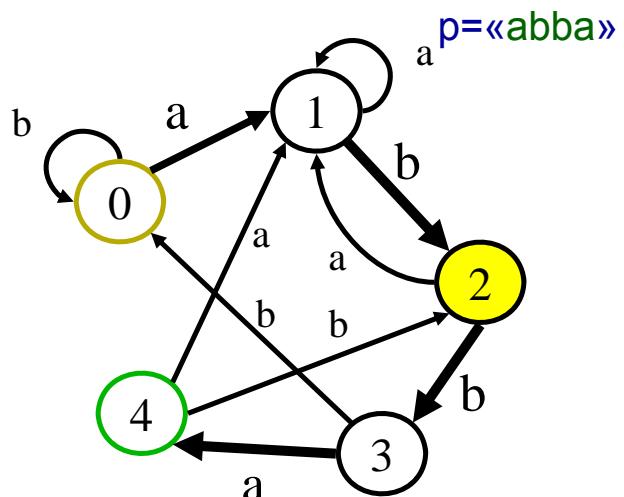

**Q** is a set of accepting states

$\Sigma$ : input alphabet

$\delta: Q \times \Sigma \rightarrow Q$ : transition function

| input | a | b |
|-------|---|---|
| state | 0 | 1 |
| 0     | 1 | 0 |
| 1     | 1 | 2 |
| 2     | 1 | 3 |
| 3     | 4 | 0 |
| 4     | 1 | 2 |

CS463 - Information Retrieval Systems

Yannis Tzitzikas, U. of Crete

49

## Example (IX)

**Q** is a finite set of states

$q_0 \in Q$  is the start state

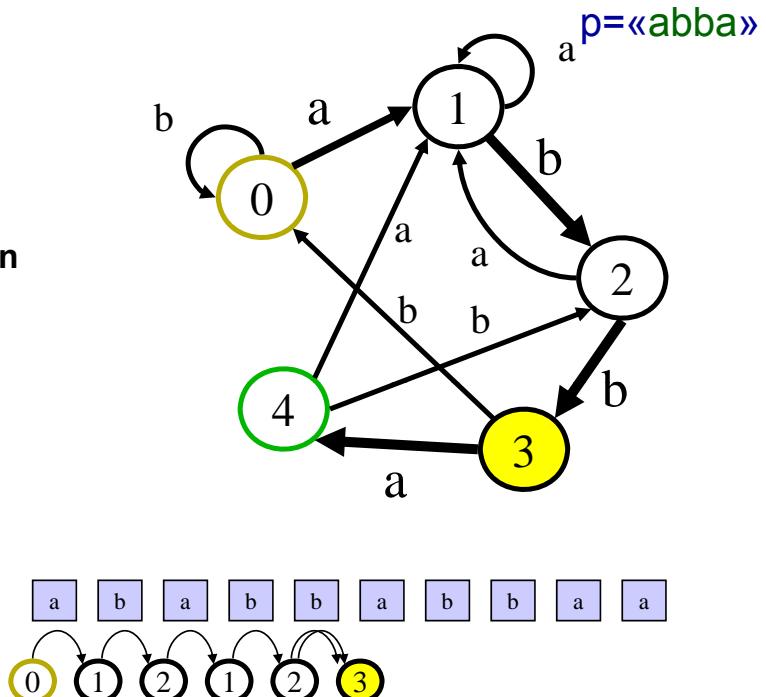

**Q** is a set of accepting states

$\Sigma$ : input alphabet

$\delta: Q \times \Sigma \rightarrow Q$ : transition function

| input | a | b |
|-------|---|---|
| state | 0 | 1 |
| 0     | 1 | 0 |
| 1     | 1 | 2 |
| 2     | 1 | 3 |
| 3     | 4 | 0 |
| 4     | 1 | 2 |

CS463 - Information Retrieval Systems

## Finite-Automaton-Matcher

For every pattern P of length m there exists an automaton with m+1 states that solves the pattern matching problem with the following algorithm:

```
Finite-Automaton-Matcher(T,δ,P)
n := length(T)
q := 0 // initial state
for i =1 to n do
    q := δ(q,T[i]) // transition to the next state
    if q = m then // if we reached the state m (which is the final)
        return "Pattern occurs at position " i-m
    fi
od
```

## Computing the Transition Function: It is actually the idea of KMP

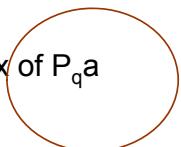

# How to Compute the Transition Function?

- Let  $P_k$  denote the first  $k$  letter string of  $P$  (i.e. the prefix of  $P$  with length  $k$ )

Compute-Transition-Function( $P, \Sigma$ )

```
m := length(P)
for q = 0 to m do
    for each character a ∈ Σ do
        k := 1+min(m,q+1)
        repeat
            k := k-1
        until  $P_k$  is a suffix of  $P_q a$ 
        δ(q,a) := k
    od
od
```

## Boyer-Moore (BM)

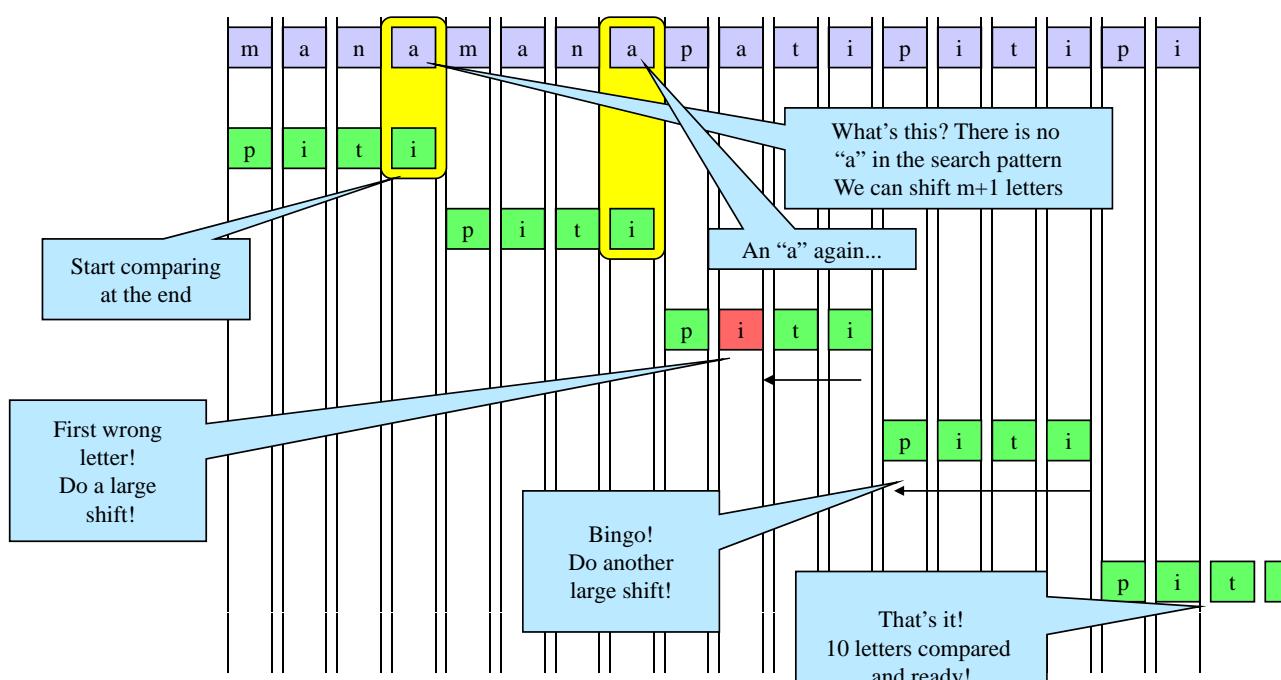

## Boyer-Moore (BM) [1975]

- Motivation
  - KMP yields genuine benefits only if a mismatch is preceded by a partial match of some length
    - only in this case the pattern slides more than one position
  - Unfortunately, this is the exception rather than the rule
    - matches occur much more seldom than mismatches
- The idea
  - start comparing characters at the end of the pattern rather than at the beginning
  - like in KMP, a pattern is pre-processed

## Boyer-Moore: The idea by an example

# Sequential Text Searching Synopsis

find the first occurrence (or all occurrences)  
of a string (or pattern)  $p$  (of length  $m$ ) in a string  $s$  (of length  $n$ )

- Brute Force Algorithm
  - $O(n^2)$  running time (worst case)
- KMP ~ Finite Automaton Matcher
  - Let a (finite) automaton do the job
    - Cost: cost to construct the automaton plus the cost to “consume” the string  $s$
  - $O(m+n)$  running time (worst case)
    - $m$ : for constructing the next table
    - $n$ : for searching the text
- BM Algorithm
  - Bad letters allow us to jump through the text
  - Faster in practice
  - $O(nm)$  running time (worst case)
  - $O(n \log(m)/m)$  average time

## Other string searching algorithms

- Rabin-Karp
- Shift-Or (it is sketched in the Modern Information Retrieval Book)
- ...and many others ..
- ..

- **Answering Pattern-Matching Queries**

# Answering Pattern Matching Queries

- Searching Allowing Errors (**Levenshtein** distance)
- Searching using Regular Expressions

## Searching Allowing Errors

- Δεδομένα:
  - Ένα κείμενο (string)  $T$ , μήκους  $n$
  - Ένα pattern  $P$  μήκους  $m$
  - Κ επιτρεπόμενα σφάλματα
- Ζητούμενο:
  - Βρες όλες τις θέσεις του κειμένου όπου το pattern  $P$  εμφανίζεται με το πολύ κ σφάλματα

Remember: Edit (Levenstein) Distance:

Minimum number of character *deletions*, *additions*, or *replacements* needed to make two strings equivalent.

“misspell” to “mispell” is distance 1

“misspell” to “mistell” is distance 2

“misspell” to “misspelling” is distance 3

## Searching Allowing Errors

- **Naïve algorithm**

- Produce all possible strings that could match P (assuming k errors) and search each one of them on T

## Searching Allowing Errors: Solution using **Dynamic Programming**

- Dynamic Programming is the class of algorithms, which includes the most commonly used algorithms in speech and language processing.
- Among them the **minimum edit distance algorithm for spelling error correction**.
- Intuition:
  - *a large problem can be solved by properly combining the solutions to various subproblems.*

## Searching Allowing Errors: Solution using Dynamic Programming (II)

*Problem Statement: T[n] text string, P[m] pattern, k errors*

Example: T = “surgery”, P = “survey”, k=2

*To explain the algorithm we will use a  $m \times n$  matrix C*

one row for each char of P, one column for each char of T

(latter on we shall see that we need less space)

|   |   | s | u | r | g | e | r | y |
|---|---|---|---|---|---|---|---|---|
| P | s |   |   |   |   |   |   |   |
|   | u |   |   |   |   |   |   |   |
|   | r |   |   |   |   |   |   |   |
|   | v |   |   |   |   |   |   |   |
|   | e |   |   |   |   |   |   |   |
|   | y |   |   |   |   |   |   |   |

## Searching Allowing Errors: Solution using Dynamic Programming (III)

T = “surgery”, P = “survey”, k=2

οι γραμμές του C εκφράζουν πόσα γράμματα του pattern έχουμε ήδη καταναλώσει  
(στη 0-γραμμή τίποτα, στη m-γραμμή ολόκληρο το pattern)

C[0,j] := 0 for every column j

(no letter of P has been consumed)

C[i,0] := i for every row i

(i chars of P have been consumed, pointer of T at 0. So i errors (insertions) so far)

T

|   |   | s | u | r | g | e | r | y |
|---|---|---|---|---|---|---|---|---|
| P | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
|   | s | 1 |   |   |   |   |   |   |
|   | u | 2 |   |   |   |   |   |   |
|   | r | 3 |   |   |   |   |   |   |
|   | v | 4 |   |   |   |   |   |   |
|   | e | 5 |   |   |   |   |   |   |
|   | y | 6 |   |   |   |   |   |   |

## Searching Allowing Errors: Solution using Dynamic Programming (IV)

```
if P[i]=T[j] THEN C[i,j] := C[i-1,j-1]
// εγινε match áρα τα “λάθη” ήταν óσα και πριν
Else C[i,j] := 1 + min of:
• C[i-1,j]
– // i-1 chars consumed P, j chars consumed of T
– // ~delete a char from T
• C[i,j-1]
– // i chars consumed P, j-1 chars consumed of T
– // ~ delete a char from P
• C[i-1,j-1]
– // i-1 chars consumed P, j-1 chars consumed of T
– // ~ character replacement
```

## Searching Allowing Errors: Solution using Dynamic Programming: Example

- T = “surgery”, P = “survey”, k=2

|   |  | T |   |   |   |   |   |   |   |  |
|---|--|---|---|---|---|---|---|---|---|--|
|   |  | s | u | r | g | e | r | y |   |  |
|   |  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |  |
| P |  | s | 1 | 0 | 1 | 1 | 1 | 1 | 1 |  |
|   |  | u | 2 | 1 | 0 | 1 | 2 | 2 | 2 |  |
|   |  | r | 3 | 2 | 1 | 0 | 1 | 2 | 3 |  |
|   |  | v | 4 | 3 | 2 | 1 | 1 | 2 | 3 |  |
|   |  | e | 5 | 4 | 3 | 2 | 2 | 1 | 3 |  |
|   |  | y | 6 | 5 | 4 | 3 | 3 | 2 | 2 |  |

## Solution using Dynamic Programming: Example

- T = “surgery”, P = “survey”, k=2

|   |   | T |   |   |   |   |   |   |  |
|---|---|---|---|---|---|---|---|---|--|
|   |   | s | u | r | g | e | r | y |  |
| P | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |  |
|   | s | 1 | 0 | 1 | 1 | 1 | 1 | 1 |  |
|   | u | 2 | 1 | 0 | 1 | 2 | 2 | 2 |  |
|   | r | 3 | 2 | 1 | 0 | 1 | 2 | 3 |  |
|   | v | 4 | 3 | 2 | 1 | 1 | 2 | 3 |  |
|   | e | 5 | 4 | 3 | 2 | 2 | 1 | 2 |  |
|   | y | 6 | 5 | 4 | 3 | 3 | 2 | 2 |  |

## Solution using Dynamic Programming: Example

- T = “surgery”, P = “survey”, k=2

|   |   | T |   |   |   |   |   |   |  |
|---|---|---|---|---|---|---|---|---|--|
|   |   | s | u | r | g | e | r | y |  |
| P | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |  |
|   | s | 1 | 0 | 1 | 1 | 1 | 1 | 1 |  |
|   | u | 2 | 1 | 0 | 1 | 2 | 2 | 2 |  |
|   | r | 3 | 2 | 1 | 0 | 1 | 2 | 3 |  |
|   | v | 4 | 3 | 2 | 1 | 1 | 2 | 3 |  |
|   | e | 5 | 4 | 3 | 2 | 2 | 1 | 2 |  |
|   | y | 6 | 5 | 4 | 3 | 3 | 2 | 2 |  |

## Solution using Dynamic Programming: Example

- T = “surgery”, P = “survey”, k=2

|   |   | T |   |   |   |   |   |   |  |
|---|---|---|---|---|---|---|---|---|--|
|   |   | s | u | r | g | e | r | y |  |
| P | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |  |
|   | s | 1 | 0 | 1 | 1 | 1 | 1 | 1 |  |
|   | u | 2 | 1 | 0 | 1 | 2 | 2 | 2 |  |
|   | r | 3 | 2 | 1 | 0 | 1 | 2 | 3 |  |
|   | v | 4 | 3 | 2 | 1 | 1 | 2 | 3 |  |
|   | e | 5 | 4 | 3 | 2 | 2 | 1 | 2 |  |
|   | y | 6 | 5 | 4 | 3 | 3 | 2 | 2 |  |

## Solution using Dynamic Programming: Example

- T = “surgery”, P = “survey”, k=2

|   |   | T |   |   |   |   |   |   |  |
|---|---|---|---|---|---|---|---|---|--|
|   |   | s | u | r | g | e | r | y |  |

## Solution using Dynamic Programming: Example

- $T = \text{"surgery"}$ ,  $P = \text{"survey"}$ ,  $k=2$

|   |   | T |   |   |   |   |   |   |  |
|---|---|---|---|---|---|---|---|---|--|
|   |   | s | u | r | g | e | r | y |  |
| P |   | 0 | 0 | 0 | 0 | 0 | 0 | 0 |  |
|   | s | 1 | 0 | 1 | 1 | 1 | 1 | 1 |  |
|   | u | 2 | 1 | 0 | 1 | 2 | 2 | 2 |  |
|   | r | 3 | 2 | 1 | 0 | 1 | 2 | 2 |  |
|   | v | 4 | 3 | 2 | 1 | 1 | 2 | 3 |  |
|   | e | 5 | 4 | 3 | 2 | 2 | 1 | 2 |  |
|   | y | 6 | 5 | 4 | 3 | 3 | 2 | 2 |  |

## Solution using Dynamic Programming: Example

- $T = \text{"surgery"}$ ,  $P = \text{"survey"}$ ,  $k=2$

|   |   | T |   |   |   |   |   |   |  |
|---|---|---|---|---|---|---|---|---|--|
|   |   | s | u | r | g | e | r | y |  |
| P |   | 0 | 0 | 0 | 0 | 0 | 0 | 0 |  |
|   | s | 1 | 0 | 1 | 1 | 1 | 1 | 1 |  |
|   | u | 2 | 1 | 0 | 1 | 2 | 2 | 2 |  |
|   | r | 3 | 2 | 1 | 0 | 1 | 2 | 2 |  |
|   | v | 4 | 3 | 2 | 1 | 1 | 2 | 3 |  |
|   | e | 5 | 4 | 3 | 2 | 2 | 1 | 2 |  |
|   | y | 6 | 5 | 4 | 3 | 3 | 2 | 2 |  |

Bold entries indicate matching positions.

- Cost:  $O(mn)$  time where  $m$  and  $n$  are the lengths of the two strings being compared.
- Παρατήρηση: η πολυπλοκότητα είναι ανεξάρτητη του  $k$

## Solution using Dynamic Programming: Example

- $T = \text{"surgery"}$ ,  $P = \text{"survey"}$ ,  $k=2$

|   |   | T |   |   |   |   |   |   |  |
|---|---|---|---|---|---|---|---|---|--|
|   |   | s | u | r | g | e | r | y |  |
| P | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |  |
|   | s | 1 | 0 | 1 | 1 | 1 | 1 | 1 |  |
|   | u | 2 | 1 | 0 | 1 | 2 | 2 | 2 |  |
|   | r | 3 | 2 | 1 | 0 | 1 | 2 | 3 |  |
|   | v | 4 | 3 | 2 | 1 | 1 | 2 | 3 |  |
|   | e | 5 | 4 | 3 | 2 | 2 | 1 | 2 |  |
|   | y | 6 | 5 | 4 | 3 | 3 | 2 | 2 |  |

- Cost:  $O(mn)$  time where  $m$  and  $n$  are the lengths of the two strings being compared.
- **$O(m)$  space** as we need to keep only the previous column stored
  - So we do not have to keep a  $mxn$  matrix

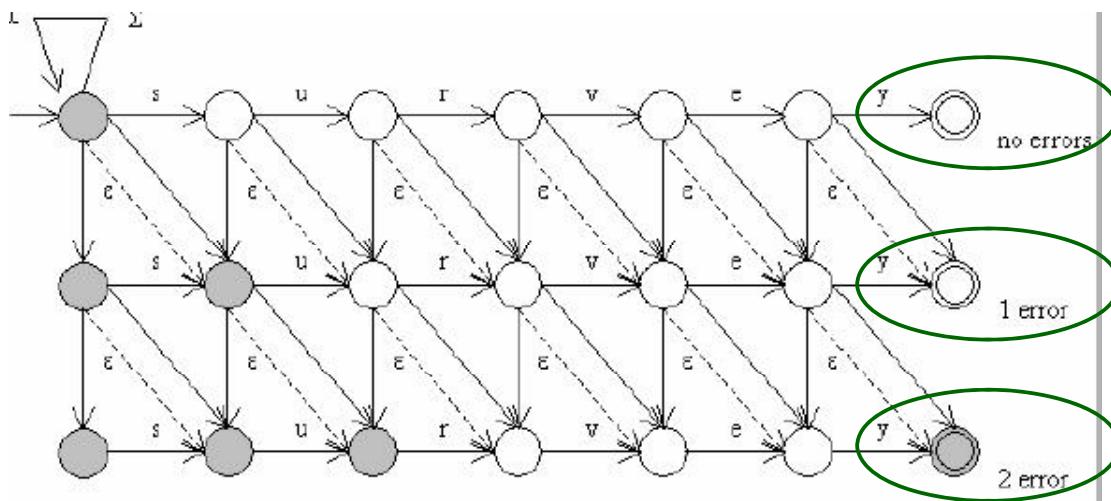

## Εφαρμογή στο groogle

The screenshot shows the grOOGLE search engine interface. The search bar contains the Greek word "Πανεπιστήμιο". Below the search bar are buttons for "Search", "Advanced Search", and "clustering". A dropdown menu shows "10 results per page". Below the search area, a message states: "list of documents matching the search" and "Your search - Πανεπιστήμιο - did not match any documents." A "Did you mean ?" section suggests the misspelling "πανεπιστημιο". A green arrow points from the text "Did you mean ?" to the suggested correction "πανεπιστημιο".

## Searching Allowing Errors Solution with a Nondeterministic Automaton

## Searching Allowing Errors: Solution with a Nondeterministic Automaton

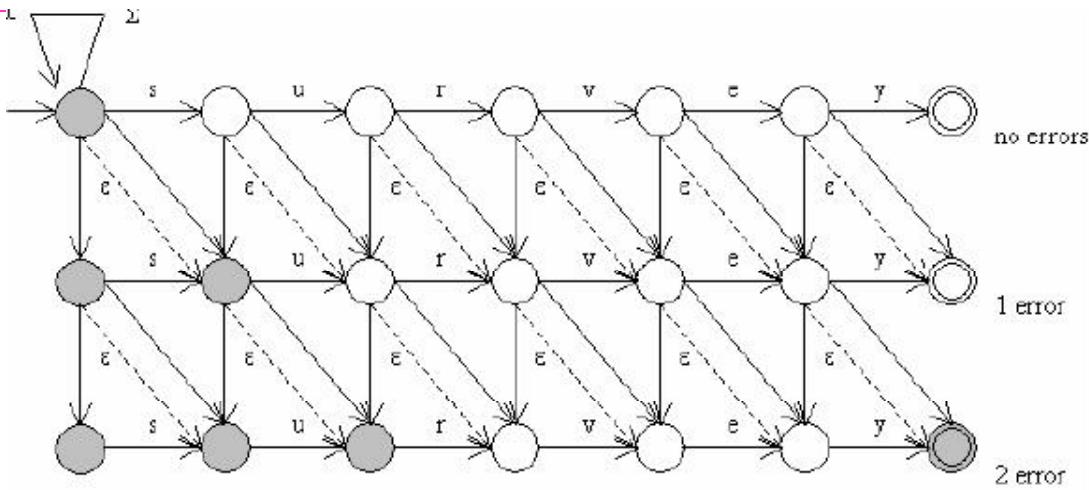

- At each iteration, a new text character is read and automaton changes its state.

- Every row denotes the number of errors seen
  - (0 for the first row, 1 for the second, and so on)
- Every column represents matching to pattern up to a given position.

## Searching Allowing Errors: Solution with a Nondeterministic Automaton

- Horizontal arrows represents matching a document.
- Vertical arrows represent insertions into pattern
- Solid diagonal arrows represent replacements (they are unlabelled: this means that they match any character)
- Dashed diagonal arrows represent deletion in the pattern ( $\epsilon$ : empty).

## Searching Allowing Errors: Solution with a Nondeterministic Automaton

- Search time is  $O(n)$ 
  - άρα η μέθοδος αυτή είναι πιο αποδοτική από την τεχνική με δυναμικό προγραμματισμό (που ήταν  $O(mn)$ )
- However, if we convert NDFA into a DFA then it will be huge in size
  - An alternative solution is **BIT-Parallelism**

## Searching using Regular Expressions

## Searching using Regular Expressions

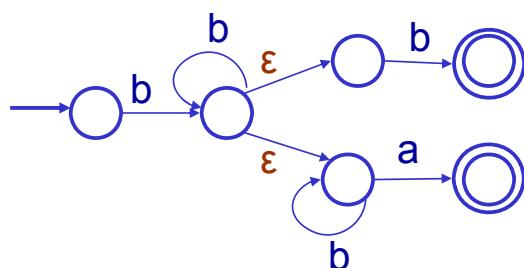

### Classical Approach

- (a) Build a ND Automaton
- (b) Convert this automaton to deterministic form

- (a) Build a ND Automaton

Size  $O(m)$  where  $m$  the size of the regular expression

$$\text{Π.χ. regex} = b \ b^* \ (b \mid b^* \ a)$$

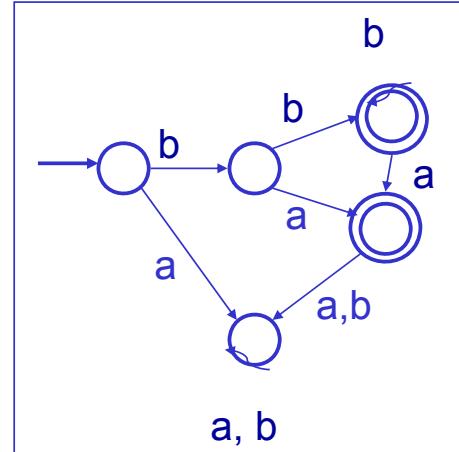

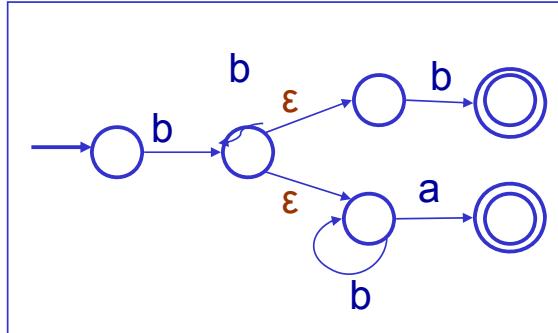

## Searching using Regular Expressions (II)

(b) Convert this automaton to deterministic form

- It can search any regular expression in  $O(n)$  time where  $n$  the size of text
- However, its size and construction time can be exponential in  $m$ , i.e.  $O(m \cdot 2^m)$ .

$$b \ b^* (b \mid b^* a) = (b \ b^* b \mid b \ b^* b^* a) = (b \ b \ b^* \mid b \ b^* a)$$

**Bit-Parallelism** to avoid constructing the deterministic automaton (NFA Simulation)

## Pattern Matching Queries and Index Structures

# Pattern Matching Using Inverted Files

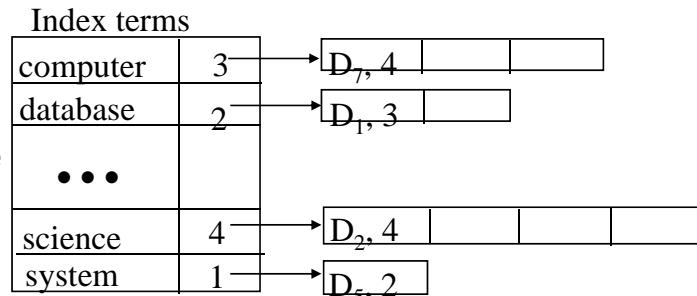

- Προηγουμένως είδαμε πως μπορούμε να αποτιμήσουμε επερωτήσεις με κριτήρια τύπου Edit Distance, RegExpr, ανατρέχοντας στα κείμενα.
  - Τι κάνουμε αν έχουμε ήδη ένα Inverted File ?
    - Ψάχνουμε το Λεξιλόγιο αντί των κειμένων (αρκετά μικρότερο σε μέγεθος)
    - Βρίσκουμε τις λέξεις που ταιριάζουν
    - Συγχωνεύουμε τις λίστες εμφανίσεων (occurrence lists) των λέξεων που ταίριαζαν.
  - If **block addressing** is used, the search must be completed with a sequential search over the blocks.
  - Technique of inverted files is not able to efficiently find approximate matches or regular expressions that span many words.

CS463 - Information Retrieval Systems

## Pattern Matching Using Suffix Trees (II)

If the suffix trees index **all text positions** (not just word beginnings) it can search for words, prefixes, suffixes and sub-strings with the same search algorithm and cost described for word search.

Indexing all text positions normally makes the suffix array size **10 times or more the text size.**

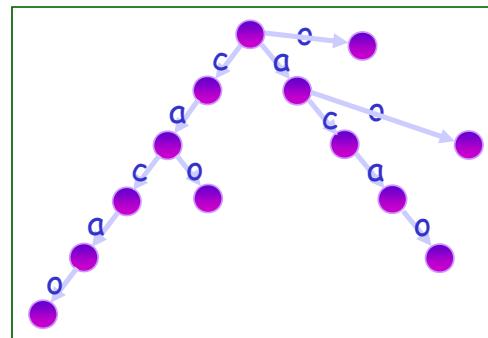

cacao

if word beginnings

## Pattern Matching Using Suffix Trees (III)

- **Range queries** are easily solved by just searching both extremes in the trie and then collecting all the leaves lie in the middle.

Consider the query: “letter” < q < “many” where < has a lexicographic meaning

## Pattern Matching Using Suffix Trees (IV)

- **Regular expressions** can be searched in the suffix tree. The algorithm simply simulates sequential searching of the regular expression

$q=ma^*$

## Some Software Packages for String Searching

- A recent software package that implements several recently emerged string matching algorithms (code available in C++) is available at:
  - <http://flamingo.ics.uci.edu/releases/1.0/>
- StringSearch: Searching algorithms written in Java (includes implementations of the Boyer-Moore and the Shift-Or (bit-parallel) algorithms). These algorithms are easily five to ten times faster than the naïve implementation found in `java.lang.String`. Available at
  - <http://johannburkard.de/software/stringsearch/>
- Algorithm FJC in Java
  - <http://www.sfu.ca/~cjenning/fjs/index.html>
