Lecture 18: Alias analysis Unification

Polyvios Pratikakis

Computer Science Department, University of Crete

Type Systems and Programming Languages

Pratikakis (CSD)

< □ > < 凸

Introduction

- Aliasing occurs when different names refer to the same thing
 - Typically, we only care for imperative programs
 - The usual culprit: pointers
- A core building block for other analyses
 - For example in *p = 3; what does p point to?
- Useful for many languages
 - ► C lots of pointers all over the place
 - Java "objects" point to updatable memory
 - ML ML has updatable references

Alias analysis

- Alias analysis answers the question
 Do pointers p and q alias the same address?
- Unfortunately, undecidable
 - Remember Rice's theorem: No program can precisely decide anything interesting about arbitrary source code
- Usual solution: allow imprecision
 - Decision problem: yes/no undecidable
 - Approximation: yes/no/maybe decidable

May alias analysis

- p and q may alias if it is possible that p and q might point to the same address
- Negative answer is precise
 - "yes" imprecise, means p and q might alias
 - "no" precise, means p and q never alias
- $\bullet~$ If p~ may not alias q, then a write through p~ does not affect memory pointed to by q~

*p = 3; x = *q; means write through p does not affect x

• What is the most conservative may-alias analysis?

Must alias analysis

- p and q must alias if they do point to the same address
- Positive answer is precise
 - "yes" precise, means p and q definitely alias
 - "no" imprecise, means p and q might not alias
- If p must alias q, then a write through p always affects memory pointed to by q

*p = 3; x = *q; means x is 3

• What is the most conservative must-alias analysis?

Early alias analysis

- By Landi and Ryder
- Expressed as computing alias pairs
 - ▶ E.g., (*p, *q) means p and q may point to the same memory
- Issues?
 - There could be many alias pairs

★ (*p, *q), (p->a, q->a), (p->b, q->b), ...

What about cyclic data structures?

* (*p, p->next), (*p, p->next->next), ...

6/33

< □ > < □ > < □ > < □ > < □ > < □ >

Points-to analysis

• Determine the set of locations that p may point to

- E.g., (p, $\{\&x\}$) means p may point to the location of x
- ► To decide if p and q alias, see if their points-to sets overlap
- More compact representation
 - The same aliasing information takes less memory
 - Analysis scales better
- We must name all locations in the program
 - Pick a finite set of location names
 - ★ No problem with cyclic data structures
 - x = malloc(...); where does x point to?
 - ★ (x, {malloc@42}) "the malloc() at line 42"

Flow-sensitivity

- An analysis is *flow-sensitive* if it computes the answer *at every program point*
 - We saw that dataflow analysis is flow-sensitive
- An analysis is *flow-insensitive* if it does not depend on the order of statements
 - We saw that type systems are flow-insensitive
- Flow-sensitive alias/points-to analysis is much more precise
- ...but also much more expensive
- Flow-insensitive alias analysis is much faster

Example

- Assume the program
 - p = &x; p = &y; *p = &z;
- Flow-sensitive analysis solution per program point
 - $p = \&x; // (p, \{\&x\}) \\ p = \&y; // (p, \{\&y\}) \\ *p = \&z; // (p, \{\&y\}), (y, \{\&z\})$
- Flow-insensitive analysis one solution

 $(p, \{\&x, \&y\})$ $(x, \{\&z\})$ $(y, \{\&z\})$

Label flow analysis

- A way to compute points-to information
- We extend references with labels
 - $e ::= \ldots | \operatorname{ref}^r e | \ldots$
 - ► A label *r* identifies this particular allocation instruction
 - ★ Like *malloc*@42 identifies a point in the program
 - ★ Drawn from a finite set of labels
 - For now, the programmers add these labels
- Goal of points-to analysis: find the set of labels a pointer may refer to
 - For example:

```
let x = ref^{R_x} 0 in
let y = x in
y := 3 (* y may point to \{R_x\} *)
```

4 2 5 4 2 5

Type-based alias analysis

- We will build an alias analysis using the type system
 - Similar to OCaml's type inference
- We use *labeled types* in the analysis
 - ▶ Extend reference types with labels: *T* ::= ... | *Ref*^{*r*} *T* | ...
 - ▶ To find the location at a pointer dereference !e or assignment e := ...
 - ★ Find the type *T* of *e* (which must be a reference)
 - $\star\,$ We look at the reference type to decide which location might be accessed

A B A A B A

Type system (with labels)

$$[\text{T-Ref}] \frac{\Gamma \vdash e: T}{\Gamma \vdash \mathsf{ref}^r \; e: \operatorname{Ref}^r T}$$

$$[\text{T-Deref}] \frac{\Gamma \vdash e : Ref' T}{\Gamma \vdash !e : T}$$

$$[\text{T-Assign}] \frac{\Gamma \vdash e_1 : Ref^{\text{r}} T}{\Gamma \vdash e_2 : T}$$
$$[\text{T-Assign}] \frac{\Gamma \vdash e_2 : T}{\Gamma \vdash e_1 := e_2 : Unit}$$

Alias analysis

CS546, 2024-2025

・ロト ・ 日 ・ ・ ヨ ・ ・ ヨ ・

Example

In the previous program

 $\begin{array}{ll} \textbf{let} \ x = ref^{R_x} \ 0 \ \textbf{in} \\ \textbf{let} \ y = x \ \textbf{in} \\ y \ := 3 \end{array}$

- x has type $Ref^{R_x} Nat$
- y has the same type as x
- Therefore, at the assignment expression, we know which location y points to

∃ ► < ∃ ►</p>

Another example

Consider the program

```
let x = \operatorname{ref}^{R} 1 in

let y = \operatorname{ref}^{R} 2 in

let w = \operatorname{ref}^{R_{w}} 0 in

let z = \operatorname{if} true then x else y in

z := 3
```

- Here, x and y both have type $\operatorname{Ref}^{R} \operatorname{Nat}$
 - They must have the same type because of the if
- At assignment, we write to location R
 - We do not know which location this is exactly, x or y
 - But we know it cannot affect w

And another example

Another program

let $x = ref^R 0$ in let $y = ref^{R_y} x$ in let $z = ref^R 2$ in y := z

- Both x and z have the same label
 - * They must have the same type because of the pointed type of y
- We do not know whether y points to x or y

Things to notice

- We have a finite set of labels
 - At most one label for each occurrence of a ref in the program
 - A label may represent more than one run-time locations
- Whenever two labels "meet" in the type system, they must be the same
 - Can you see where this happens in the type-rules?
- The system is flow-insensitive
 - Types don't change after assignment

Type inference

- In practice, the programmer does not write the labels
 - We need to infer them
- Given an unlabeled program that satisfies the standard type system, is there a labeling that satisfies the labeled type system?
 - That labeling is the analysis result

Checking vs. inference

- Type checking
 - The programmer annotates the program with types
 - Typing checks that the annotations are correct
 - It is "obvious" how to check
- Type inference
 - The programmer does not annotate the program
 - Typing tries to discover correct types
 - It is not "obvious", requires more work to check
- Consider the type-system of C
 - C requires type annotations only at function types and local variable declarations
 - ★ 3+4 does not need a type annotation
 - Trade-off: programmer annotations vs. computed types

A type inference algorithm

• A standard approach in type inference

- Type the program by introducing variables at any point when an annotation is missing
 - ★ We will use *label variables* ρ here
- Typing the unlabeled program does two things
 - Introduces label variables in all Ref types
 - Creates constraints among labels
- Solve the constraints to find a labeling
 - No solution means no valid labeling: type error
 - Alias analysis solution always exists: everything aliases

- Problem 1: What label to assign to the reference at [T-REF]?
- Solution: Introduce a fresh, unknown variable

$$[\text{T-Ref}] \frac{\Gamma \vdash e: \mathcal{T} \quad \rho - \text{fresh}}{\Gamma \vdash \text{ref } e: \operatorname{Ref}^p \mathcal{T}}$$

• Why a variable and not a constant?

Step 1: Introduce labels (cont'd)

• Problem 2: What type to give to function arguments?

- ► Type language *T* uses labeled reference types *Ref^p T*
- But the programmer uses unlabeled types Ref T
- Solution:
 - Use two type languages
 - ★ Standard $S ::= S \rightarrow S \mid Nat \mid Bool \mid Unit \mid Ref S$
 - ★ Labeled $T ::= T \rightarrow T \mid Nat \mid Bool \mid Unit \mid Ref^{p} T$
 - Annotate type S with fresh labels to get a T

* We write this as
$$T = \operatorname{fresh}(S)$$

$$\Gamma, x : T \vdash e : T'$$

$$T = \operatorname{fresh}(S)$$

$$\Gamma \vdash \lambda x : S.e : T \to T'$$

Step 2: Generate constraints

• Problem 3: Some rules implicitly require types to be equal

- Solution: Make this explicit using *equality constraints*
 - We write equality constraints as premises $T_1 = T_2$
 - Each such premise is not checked, instead produces a constraint
 - We solve all generated constraints together after typing

• Rule [T-IF] requires both branches to have the same type

$$\begin{array}{c} \Gamma \vdash e: Bool \\ \Gamma \vdash e_1: T_1 \\ \Gamma \vdash e_2: T_2 \\ T_1 = T_2 \end{array}$$

$$[\text{T-IF}] \hline \Gamma \vdash \text{if } e \text{ then } e_1 \text{ else } e_2: T_1 \end{array}$$

Step 2: Generate constraints (cont'd)

• Rule [T-Assign] requires that the assigned value has the same type as the pointer

$$[\text{T-ASSIGN}] \frac{ \Gamma \vdash e_1 : Ref \ T_1 }{ \Gamma \vdash e_2 : T_2 } \frac{ T_1 = T_2 }{ \Gamma \vdash e_1 := e_2 : Unit }$$

- We assume that e_1 always has a pointer type
 - That is always true
 - We assume the program typechecks with standard types

Step 2: Generate constraints (cont'd)

• Rule [T-APP] requires the formal and actual arguments to have the same type

$$\begin{array}{c} \Gamma \vdash e_1 : T_1 \rightarrow T' \\ \Gamma \vdash e_2 : T_2 \\ T_1 = T_2 \end{array} \\ \hline \Gamma \vdash (e_1 \ e_2) : T' \end{array}$$

- Again, we assume e_1 has a function type
 - As before, this is always true
 - Because the program typechecks with standard types

• After applying the type rules, we are left with a set of equality constraints

 $\blacktriangleright T_1 = T_2$

- We solve these constraints using rewriting
- Each rewriting step simplifies a constraint into simpler constraints
- C => C' rewrites the set C of all constraints to constraints C'

Step 3: Solve the constraints (cont'd)

- $C \cup \{Nat = Nat\} \Longrightarrow C$
- $C \cup \{Bool = Bool\} \Longrightarrow C$
- $C \cup \{ \textit{Unit} = \textit{Unit} \} => C$
- $C \cup \{T_1 \to T_2 = T'_1 \to T'_2\} => C \cup \{T_1 = T'_1\} \cup \{T_2 = T'_2\}$
- $C \cup \{ Ref^{\rho_1} \ T_1 = Ref^{\rho_2} \ T_2 \} => C \cup \{ T_1 = T_2 \} \cup \{ \rho_1 = \rho_2 \}$
- $C \cup \{\text{mismatched constructors}\} => \text{error}$
 - Cannot happen if we start with a program that typechecks with standard types
- This algorithm always terminates
- When no further reduction applies, we have only label equalities

29/33

Last step: Use solution to add constants

- Compute the sets of labels that are equal
 - Using union-find
- Create a constant label R for each equivalence class of label variables
- Two pointers alias if their types refer to the same constant label

Example

Program	Variable types:
let $x = ref 1$ in	× : Ref ^e Nat
let $y = ref 2$ in	$y : Ref^b Nat$
let $z = ref 3$ in	$z : Ref^c Nat$
let $w = if$ true then x else y in	w : Ref^{a} Nat
w := 42	·

- Typing annotates each ref expression with a variable a, b, c
- Typing the if creates equality constraint Ref^{a} $Nat = Ref^{b}$ Nat
- Solving the constraint gives a = b
- Two equivalence classes: $\{a, b\}$ and $\{c\}$
 - Create two constants R_1 and R_2 for the equivalence classes

Example (cont'd)

Annotated programVariable types:let $x = ref^{R_1} 1$ in $x : Ref^{R_1} Nat$ let $y = ref^{R_1} 2$ in $y : Ref^{R_1} Nat$ let $z = ref^{R_2} 3$ in $z : Ref^{R_2} Nat$ let w = if true then x else y in $w : Ref^{R_1} Nat$ w := 42

- The assignment writes to one of the locations labeled by R_1
- Result: x, y and w may alias either of the first two allocated locations, but z cannot
 - May alias: their types have the same location label

Steensgaard's Analysis

- Flow-insensitive
- Inter-procedural
 - Can analyze multiple functions together
- Context-insensitive
 - Does not discriminate between different calls to the same function
- Unification-based
 - Analysis named after Bjarne Steensgaard (1996)
 - ► In practice: implementation for C handles type casts, etc.
- Properties
 - Very scalable
 - ★ What is its complexity?
 - Imprecise
