

## Digraphs

- A digraph is a graph whose edges are all directed
- Short for "directed graph"
- Applications
- one-way streets
- flights
- task scheduling

## Digraph Properties

- A graph $G=(V, E)$ such that

- Each edge goes in one direction:
- Edge $(\mathrm{a}, \mathrm{b})$ goes from a to b , but not b to a
- If $G$ is simple, $\boldsymbol{m} \leq \boldsymbol{n} \cdot \boldsymbol{n}-1)$
- If we keep in-edges and out-edges in separate adjacency lists, we can perform listing of incoming edges and outgoing edges in time proportional to their size

## Directed DFS

- We can specialize the traversal algorithms (DFS and BFS) to digraphs by traversing edges only along their direction
- In the directed DFS algorithm, we have four types of edges
- discovery edges
- back edges
- forward edges
- cross edges
- A directed DFS starting at a vertex $s$ determines the vertices reachable from $s$

## Digraph Application

- Scheduling: edge (a,b) means task a must be completed before $b$ can be started

## The Directed DFS Algorithm

```
Algorithm DirectedDFS(G,v):
    Label v}\mathrm{ as active // Every vertex is initially unexplored
    for each outgoing edge, e, that is incident to v}\mathrm{ in }G\mathrm{ do
        if e is unexplored then
            Let w}\mathrm{ be the destination vertex for }
            if w}\mathrm{ is unexplored and not active then
                Label e as a discovery edge
                DirectedDFS(G,w)
            else if w}\mathrm{ is active then
                Label e as a back edge
            else
                Label e as a forward/cross edge
    Label v}\mathrm{ as explored
```

## Transitive Closure

- Given a digraph $\boldsymbol{G}$, the
transitive closure of $\boldsymbol{G}$ is the digraph $G^{*}$ such that
- $G^{*}$ has the same vertices as $\boldsymbol{G}$
- if $G$ has a directed path from $u$ to $v(u \neq v), G^{*}$ has a directed edge from $\boldsymbol{u}$ to $\boldsymbol{v}$
- The transitive closure provides reachability information about a digraph

Directed Graphs

## Strongly Connected Components

- Maximal subgraphs such that each vertex can reach all other vertices in the subgraph
- Can also be done in $O(n+m)$ time using DFS, but is more complicated (similar to biconnectivity).

$\{f, d, e, b\}$

## Algorithm for Topological Sorting

- Note: This algorithm is different than the one in the book

```
Algorithm TopologicalSort(G)
    H}\leftarrow\boldsymbol{G}\quad// Temporary copy of \boldsymbol{G
    n}\leftarrow\boldsymbol{G.numVertices()
    while}H\mathrm{ is not empty do
        Let v}\mathrm{ be a vertex with no outgoing edges
        Label v}v~
            n\leftarrown-1
            Remove v from H
```

- Running time: $\mathrm{O}(\mathrm{n}+\mathrm{m})$
