Minimum Spanning Trees

1

## Application: Connecting a Network

- Suppose the remote mountain country of Vectoria has been given a major grant to install a large Wi-Fi the center of each of its mountain villages.
- Communication cables can run from the main Internet access point to a village tower and cables can also run between pairs of towers.
- The challenge is to interconnect all the towers and the Internet access point as **cheaply** as possible.

## Application: Connecting a Network

- We can model this problem using a graph,  $G$ , where each vertex in  $G$  is the location of a Wi-Fi the Internet access point, and an edge in  $G$  is a possible cable we could run between two such vertices.
- Each edge in  $G$  could then be given a weight that is equal to the cost of running the cable that that edge represents.
- Thus, we are interested in finding a connected acyclic subgraph of  $G$  that includes all the vertices of  $G$  and has minimum total cost.
- Using the language of graph theory, we are interested in finding a **minimum spanning tree (MST)** of  $G$ .

Minimum Spanning Trees

3

## Minimum Spanning Trees

- Spanning subgraph**
  - Subgraph of a graph  $G$  containing all the vertices of  $G$
- Spanning tree**
  - Spanning subgraph that is itself a (free) tree
- Minimum spanning tree (MST)**
  - Spanning tree of a weighted graph with minimum total edge weight
- Applications**
  - Communications networks
  - Transportation networks

## Cycle Property

### Cycle Property:

- Let  $T$  be a minimum spanning tree of a weighted graph  $G$
- Let  $e$  be an edge of  $G$  that is not in  $T$  and  $C$  let be the cycle formed by  $e$  with  $T$
- For every edge  $f$  of  $C$ ,  $\text{weight}(f) \leq \text{weight}(e)$

### Proof:

- By contradiction
- If  $\text{weight}(f) > \text{weight}(e)$  we can get a spanning tree of smaller weight by replacing  $e$  with  $f$

Minimum Spanning Trees

5

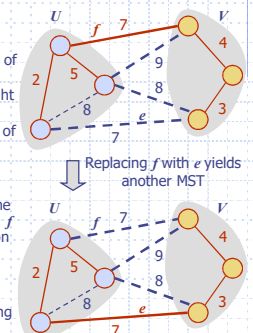

## Partition Property

### Partition Property:

- Consider a partition of the vertices of  $G$  into subsets  $U$  and  $V$
- Let  $e$  be an edge of minimum weight across the partition
- There is a minimum spanning tree of  $G$  containing edge  $e$

### Proof:

- Let  $T$  be an MST of  $G$
- If  $T$  does not contain  $e$ , consider the cycle  $C$  formed by  $e$  with  $T$  and let  $f$  be an edge of  $C$  across the partition
- By the cycle property,  $\text{weight}(f) \leq \text{weight}(e)$
- Thus,  $\text{weight}(f) = \text{weight}(e)$
- We obtain another MST by replacing  $f$  with  $e$

## Prim-Jarnik's Algorithm

- Similar to Dijkstra's algorithm
- We pick an arbitrary vertex  $s$  and we grow the MST as a cloud of vertices, starting from  $s$
- We store with each vertex  $v$  label  $d(v)$  representing the smallest weight of an edge connecting  $v$  to a vertex in the cloud
- At each step:
  - We add to the cloud the vertex  $u$  outside the cloud with the smallest distance label
  - We update the labels of the vertices adjacent to  $u$

## Prim-Jarnik Pseudo-code

```

Algorithm PrimJarnikMST( $G$ ):
  Input: A weighted connected graph  $G$  with  $n$  vertices and  $m$  edges
  Output: A minimum spanning tree  $T$  for  $G$ 
  Pick any vertex  $v$  of  $G$ 
   $D[v] \leftarrow 0$ 
  for each vertex  $u \neq v$  do
     $D[u] \leftarrow +\infty$ 
  Initialize  $T \leftarrow \emptyset$ 
  Initialize a priority queue  $Q$  with an item  $((u, \text{null}), D[u])$  for each vertex  $u$ ,
  where  $(u, \text{null})$  is the element and  $D[u]$  is the key.
  while  $Q$  is not empty do
     $(u, e) \leftarrow Q.\text{removeMin}()$ 
    Add vertex  $u$  and edge  $e$  to  $T$ .
    for each vertex  $z$  adjacent to  $u$  such that  $z$  is in  $Q$  do
      // perform the relaxation procedure on edge  $(u, z)$ 
      if  $w((u, z)) < D[z]$  then
         $D[z] \leftarrow w((u, z))$ 
        Change to  $(z, (u, z))$  the element of vertex  $z$  in  $Q$ .
        Change to  $D[z]$  the key of vertex  $z$  in  $Q$ .
  return the tree  $T$ 

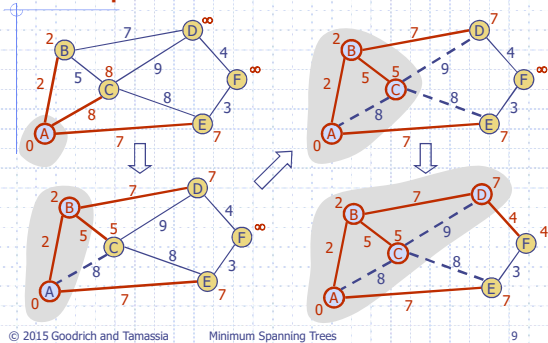

```

## Analysis

- Graph operations
  - We cycle through the incident edges once for each vertex
- Label operations
  - We set/get the distance, parent and locator labels of vertex  $z$   $O(\deg(z))$  times
  - Setting/getting a label takes  $O(1)$  time
- Priority queue operations
  - Each vertex is inserted once into and removed once from the priority queue, where each insertion or removal takes  $O(\log n)$  time
  - The key of a vertex  $w$  in the priority queue is modified at most  $\deg(w)$  times, where each key change takes  $O(\log n)$  time
- Prim-Jarnik's algorithm runs in  $O((n + m) \log n)$  time provided the graph is represented by the adjacency list structure
  - Recall that  $\sum_v \deg(v) = 2m$
- The running time is  $O(m \log n)$  since the graph is connected

Minimum Spanning Trees

11

## Kruskal's Approach

- Maintain a partition of the vertices into clusters
  - Initially, single-vertex clusters
  - Keep an MST for each cluster
  - Merge "closest" clusters and their MSTs
- A priority queue stores the edges outside clusters
  - Key: weight
  - Element: edge
- At the end of the algorithm
  - One cluster and one MST

## Kruskal's Algorithm

**Algorithm** KruskalMST( $G$ ):

**Input:** A simple connected weighted graph  $G$  with  $n$  vertices and  $m$  edges

**Output:** A minimum spanning tree  $T$  for  $G$

**for each vertex**  $v$  **in**  $G$  **do**

    Define an elementary cluster  $C(v) \leftarrow \{v\}$ .

Let  $Q$  be a priority queue storing the edges in  $G$ , using edge weights as keys  
 $T \leftarrow \emptyset$  //  $T$  will ultimately contain the edges of the MST

**while**  $T$  has fewer than  $n - 1$  edges **do**

$(u, v) \leftarrow Q.\text{removeMin}()$

    Let  $C(v)$  be the cluster containing  $v$

    Let  $C(u)$  be the cluster containing  $u$

**if**  $C(v) \neq C(u)$  **then**

        Add edge  $(v, u)$  to  $T$

        Merge  $C(v)$  and  $C(u)$  into one cluster, that is, union  $C(v)$  and  $C(u)$

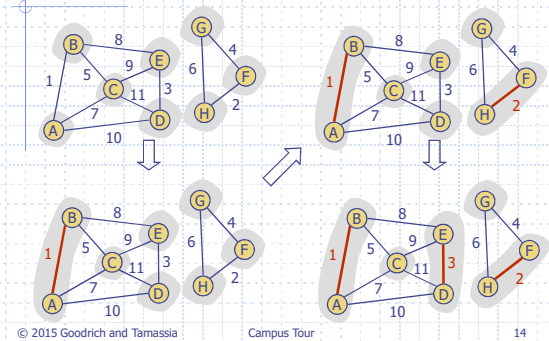

**return** tree  $T$

## Data Structure for Kruskal's Algorithm

- The algorithm maintains a forest of trees
- A priority queue extracts the edges by increasing weight
- An edge is accepted if it connects distinct trees
- We need a data structure that maintains a **partition**, i.e., a collection of disjoint sets, with operations:
  - **makeSet**( $u$ ): create a set consisting of  $u$
  - **find**( $u$ ): return the set storing  $u$
  - **union**( $A, B$ ): replace sets  $A$  and  $B$  with their union

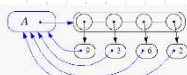

© 2015 Goodrich and Tamassia

Minimum Spanning Trees

16

## List-based Partition

- Each set is stored in a sequence
- Each element has a reference back to the set
  - operation **find**( $u$ ) takes  $O(1)$  time, and returns the set of which  $u$  is a member.
  - in operation **union**( $A, B$ ), we move the elements of the smaller set to the sequence of the larger set and update their references
  - the time for operation **union**( $A, B$ ) is  $\min(|A|, |B|)$
- Whenever an element is processed, it goes into a set of size at least double, hence each element is processed at most  $\log n$  times

Minimum Spanning Trees

17

## Partition-Based Implementation

- Partition-based version of Kruskal's Algorithm
  - Cluster merges as unions
  - Cluster locations as finds
- Running time  $O((n + m) \log n)$ 
  - Priority Queue operations:  $O(m \log n)$
  - Union-Find operations:  $O(n \log n)$

Minimum Spanning Trees

18

## Alternative Implementation

In some applications, we may be given the edges in sorted order by their weights. In such cases, we can implement Kruskal's algorithm faster than the analysis given above. Specifically, we can implement the priority queue,  $Q$ , in this case, simply as an ordered list. This approach allows us to perform all the `removeMin` operations in constant time.

Then, instead of using a simple list-based partition data structure, we can use the tree-based union-find structure given in Chapter 7. This implies that the sequence of  $O(m)$  union-find operations runs in  $O(m \alpha(n))$  time, where  $\alpha(n)$  is the slow-growing inverse of the Ackermann function. Thus, we have the following.

**Theorem 15.5:** Given a simple connected weighted graph  $G$  with  $n$  vertices and  $m$  edges, with the edges ordered by their weights, we can implement Kruskal's algorithm to construct a minimum spanning tree for  $G$  in  $O(m \alpha(n))$  time.

## Baruvka's Algorithm

- Like Kruskal's Algorithm, Baruvka's algorithm grows many clusters at once and maintains a forest  $T$
- Each iteration of the while loop halves the number of connected components in forest  $T$
- The running time is  $O(m \log n)$

**Algorithm *BaruvkaMST*( $G$ )**

```

 $T \leftarrow V$  (just the vertices of  $G$ )
while  $T$  has fewer than  $n - 1$  edges do
  for each connected component  $C$  in  $T$  do
    Let edge  $e$  be the smallest-weight edge from  $C$  to another component in  $T$ 
    if  $e$  is not already in  $T$  then
      Add edge  $e$  to  $T$ 
  return  $T$ 

```
