

Presentation for use with the textbook, **Algorithm Design and Applications**, by M. T. Goodrich and R. Tamassia, Wiley, 2015

# NP-Completeness

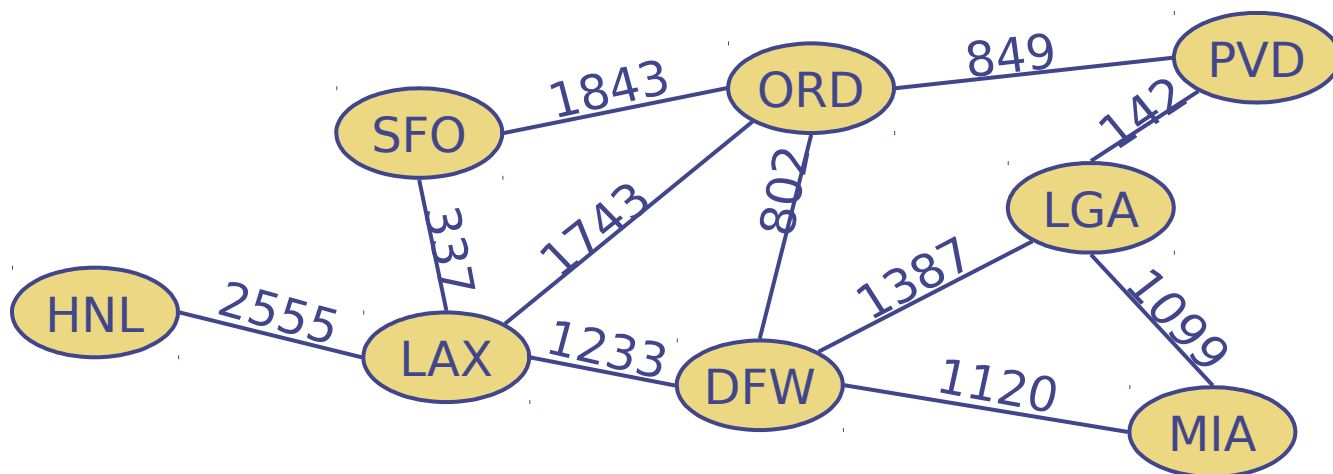

# Running Time Revisited

## ◆ Input size, $n$

- To be exact, let  $n$  denote the number of **bits** in a nonunary encoding of the input

## ◆ All the polynomial-time algorithms studied so far in this course run in polynomial time using this definition of input size.

- Exception: any pseudo-polynomial time algorithm

# Dealing with Hard Problems

◆ What to do when we find a problem that looks hard...

I couldn't find a polynomial-time algorithm;  
I guess I'm too dumb.

# Dealing with Hard Problems

◆ Sometimes we can prove a strong lower bound... (but not usually)

I couldn't find a polynomial-time algorithm,  
because no such algorithm exists!

# Dealing with Hard Problems

◆ NP-completeness let's us show collectively that a problem is hard.

I couldn't find a polynomial-time algorithm,  
but neither could all these other smart people.

# Polynomial-Time Decision Problems

- ◆ To simplify the notion of “hardness,” we will focus on the following:
  - Polynomial-time as the cut-off for efficiency
  - Decision problems: output is 1 or 0 (“yes” or “no”)
    - ◆ Examples:
      - ◆ Does a given graph  $G$  have an Euler tour?
      - ◆ Does a text  $T$  contain a pattern  $P$ ?
      - ◆ Does an instance of 0/1 Knapsack have a solution with benefit at least  $K$ ?
      - ◆ Does a graph  $G$  have an MST with weight at most  $K$ ?

# Problems and Language

- ◆ A **language**  $L$  is a set of strings defined over some alphabet  $\Sigma$
- ◆ Every decision algorithm  $A$  defines a language  $L$ 
  - $L$  is the set consisting of every string  $x$  such that  $A$  outputs “yes” on input  $x$ .
  - We say “ $A$  **accepts**  $x$ ” in this case
    - ◆ Example:
    - ◆ If  $A$  determines whether or not a given graph  $G$  has an Euler tour, then the language  $L$  for  $A$  is all graphs with Euler tours.

# The Complexity Class P

- ◆ A **complexity class** is a collection of languages
- ◆ P is the complexity class consisting of all languages that are accepted by **polynomial-time** algorithms
- ◆ For each language L in P there is a polynomial-time decision algorithm A for L.
  - If  $n=|x|$ , for  $x$  in L, then A runs in  $p(n)$  time on input  $x$ .
  - The function  $p(n)$  is some polynomial

# The Complexity Class NP

- ◆ We say that an algorithm is non-deterministic if it uses the following operation:
  - Choose(b): chooses a bit b
  - Can be used to choose an entire string y (with  $|y|$  choices)
- ◆ We say that a non-deterministic algorithm A **accepts** a string x if there exists some sequence of choose operations that causes A to output “yes” on input x.
- ◆ NP is the complexity class consisting of all languages accepted by **polynomial-time non-deterministic** algorithms.

# NP example

- ◆ Problem: Decide if a graph has an MST of weight  $K$
- ◆ Algorithm:
  1. Non-deterministically choose a set  $T$  of  $n-1$  edges
  2. Test that  $T$  forms a spanning tree
  3. Test that  $T$  has weight at most  $K$
- ◆ Analysis: Testing takes  $O(n+m)$  time, so this algorithm runs in polynomial time.

# The Complexity Class NP

## Alternate Definition

- ◆ We say that an algorithm B **verifies** the acceptance of a language L if and only if, for any  $x$  in L, there exists a certificate  $y$  such that B outputs “yes” on input  $(x,y)$ .
- ◆ NP is the complexity class consisting of all languages verified by **polynomial-time** algorithms.
- ◆ We know: P is a subset of NP.
- ◆ Major open question:  $P=NP$ ?
- ◆ Most researchers believe that P and NP are different.

# NP example (2)

- ◆ Problem: Decide if a graph has an MST of weight  $K$
- ◆ Verification Algorithm:
  1. Use as a certificate,  $y$ , a set  $T$  of  $n-1$  edges
  2. Test that  $T$  forms a spanning tree
  3. Test that  $T$  has weight at most  $K$
- ◆ Analysis: Verification takes  $O(n+m)$  time, so this algorithm runs in polynomial time.

# Equivalence of the Two Definitions

- ◆ Suppose A is a non-deterministic algorithm
  - ◆ Let  $y$  be a certificate consisting of all the outcomes of the choose steps that A uses
  - ◆ We can create a verification algorithm that uses  $y$  instead of A's choose steps
  - ◆ If A accepts on  $x$ , then there is a certificate  $y$  that allows us to verify this (namely, the choose steps A made)
  - ◆ If A runs in polynomial-time, so does this verification algorithm
- ◆ Suppose B is a verification algorithm
  - ◆ Non-deterministically choose a certificate  $y$
  - ◆ Run B on  $y$
  - ◆ If B runs in polynomial-time, so does this non-deterministic algorithm

# An Interesting Problem

- ◆ A Boolean circuit is a circuit of AND, OR, and NOT gates; the CIRCUIT-SAT problem is to determine if there is an assignment of 0's and 1's to a circuit's inputs so that the circuit outputs 1.

# CIRCUIT-SAT is in NP

- ◆ Non-deterministically choose a set of inputs and the outcome of every gate, then test each gate's I/O.

# NP-Completeness

- ◆ A problem (language)  $L$  is **NP-hard** if every problem in NP can be reduced to  $L$  in polynomial time.
- ◆ That is, for each language  $M$  in NP, we can take an input  $x$  for  $M$ , **transform** it in polynomial time to an input  $x'$  for  $L$  such that  $x$  is in  $M$  if and only if  $x'$  is in  $L$ .
- ◆  $L$  is **NP-complete** if it's in NP and is NP-hard.

# Cook-Levin Theorem

## ◆ CIRCUIT-SAT is NP-complete.

- We already showed it is in NP.

## ◆ To prove it is NP-hard, we have to show that every language in NP can be reduced to it.

- Let  $M$  be in NP, and let  $x$  be an input for  $M$ .
- Let  $y$  be a certificate that allows us to verify membership in  $M$  in polynomial time,  $p(n)$ , by some algorithm  $D$ .
- Let  $S$  be a circuit of size at most  $O(p(n)^2)$  that simulates a computer (details omitted...)

# Cook-Levin Proof

◆ We can build a circuit that simulates the verification of  $x$ 's membership in  $M$  using  $y$ .

- Let  $W$  be the working storage for  $D$  (including registers, such as program counter); let  $D$  be given in RAM "machine code."
- Simulate  $p(n)$  steps of  $D$  by replicating circuit  $S$  for each step of  $D$ . Only input:  $y$ .
- Circuit is satisfiable if and only if  $x$  is accepted by  $D$  with some certificate  $y$
- Total size is still polynomial:  $O(p(n)^3)$ .

# Some Thoughts about P and NP

- ◆ Belief:  $P$  is a proper subset of  $NP$ .
- ◆ Implication: the NP-complete problems are the hardest in  $NP$ .
- ◆ Why: Because if we could solve an NP-complete problem in polynomial time, we could solve every problem in  $NP$  in polynomial time.
- ◆ That is, if an NP-complete problem is solvable in polynomial time, then  $P=NP$ .
- ◆ Since so many people have attempted without success to find polynomial-time solutions to NP-complete problems, showing your problem is NP-complete is equivalent to showing that a lot of smart people have worked on your problem and found no polynomial-time algorithm.
