Interfacing Slightly Different Clock Frequencies:

(2) Fast-to-Show:
(α) ⇒ Remove Idle Symbols

and/or (B) => notify the transmitter, by feedback ("backpressure") to show down or wait, i.e. to insert more idle's (so that they can be removed)...

Was the Signal Sampled before or after its Change? (A) Serial Signal Sampling: (Need frampling > frignal change ) in order to "see" all signal changes) Asynchronous Signal: Sampling Instants: Samples: Since the signal changes asynchronously to the sampling clock, the sampling point "?" could have been a little before or a little after the signal changes, yielding either Ø or 1. Hence, it does not matter if the FF metastability eventually yields & or 1 - all that matters is that it becomes a valid binary value, that all of its receivers interpret in the same way.

## **Empty/Full FIFO Detection using One-Hot Pointer Encoding**

## Timing & Synchronicity of Full & Empty Flags

- Full flag Synchronous to ckwr
  - asserted as soon as a write operation fills the FIFO up (def.1 "full")
  - negated after a word is read from the FIFO and the synchronization delay elapses
- <u>Empty</u> flag Synchronous to ck<sub>rd</sub>
  - asserted <u>as soon as</u> a read operation empties the FIFO
  - negated after a word is written into the FIFO and the synchronization delay elapses
- <u>Reference</u> on Synchronization and Elastic Buffers: *W. Dally, J. Poulton: "Digital Systems Engineering"*, Cambridge University Press, 1998, ISBN 0-521-59292-5 (sections 10.2 and 10.3 –especially 10.3.4.2).

## Sampling 1-hot pointers for synchronization purposes: 1-hot/2-hot versions

- A 1-hot encoded pointer is a <u>multi-bit value</u>.
- When sampling any such value with an asynchronous clock for synchronization purposes, there is always the possibility that *some bits are sampled* "before" and some "after" they transition.
- This may result in the sampled pointer containing 2 bits ON, or 1 bit ON, or no bit ON (2-hot, or 1-hot, or 0-hot).
- 2-hot is "OK": <u>conservative</u>!
- 1-hot is normal.
- <u>0-hot is bad</u>: empty/full is not asserted even when the FIFO is in one of these states → we have to <u>ensure</u> that 0-hot <u>never happens</u>!
- ⇒ Use a 1-hot/2-hot version of the pointer for synchronization purposes: make sure that the new "hot" bit is turned ON safely before the old "hot" bit is turned OFF (e.g. use appropriate OR function of master & slave flip-flops).
